Mr. Anderson thus became the helpless victim of judicial persecution. Having been forced into heavy expenditure in defence of his personal rights he had the additional mortification of finding that the survivor of his persecutors was by a legal technicality superior to the ordinary operation of the law. Under the terrible strains and mortifications which he had courageously endured for several years Mr. Anderson, now completely ruined in purse, bore himself with unflinching courage. It would, perhaps, have been better for him—he certainly would have been a happier man—if he had ceased to struggle against the gross injustice of his fate. But this his courage and determination would not allow him to do, and he spent the remainder of a most unfortunate life in resenting the position to which the unjust and drunken colonial judges had reduced him. His efforts on behalf of general medical reform, though honestly undertaken for the sake of the rank-and-file of the medical profession, were all inspired by the abiding sense of his own wrongs. The General Medical Council, being unable to take cognisance of his case stood convicted in his eyes of ineptitude, while he was ready to maintain the illegality of its constitution and the necessity for its root and branch reform. The governing body of the Royal College of Surgeons of England, making no sustained effort to help him—a Fellow of the corporation—in his struggle, became in his eyes a body that required complete reconstruction, and his voice was among the loudest, if not among the clearest, of those who demanded for all Members of the College a proper representation on the Council. But, we regret to say, having that cause at heart, that the position of the Members lost by Mr. Anderson's advocacy. Protracted litigation, often personally conducted, had left him with a feeling concerning legal phraseology that was little short of superstition. He had found himself on many occasions opposed in his procedure by the wording rather than by the spirit of certain Acts of Parliament, certain verdicts, and certain charters. Consequently, in framing resolutions in support of various broad schemes of medical reform, he was wont to make his motions so elaborate in their provision against possible misconception that they became to the ordinary understanding mere involved verbiage. The medical profession cannot be blamed for withholding serious support from propositions so incoherent as those for which Mr. Anderson was wont to stand sponsor upon all public occasions.

But it would be an injustice to the memory of a brave and deeply wronged man if his character were to be finally judged by some of his later acts and utterances. Impelled, as no doubt he was, by his private wrongs to take up the rôle of public champion of the rights of his profession, from the time that the grievances which he desired to redress were public and not private ones he ceased to obtrude his personal wrongs; while as a reformer the line which he took was fairly correct, though his methods were more than occasionally wrong-headed. With his death is closed a lurid page in the constitutional history of this country. Mr. Anderson was ruined by unjust judges, and this not under some corrupt Oriental autocrat with a mediæval scheme of misrule, but less than a decade ago under the British Crown.

GEORGE CORDWENT, M.D. ST. AND., F.R.C.S. ENG., L.S.A.

DR. GEORGE CORDWENT died at his residence, Milverton, Somerset, on Nov. 12th in his eighty-sixth year. Dr. Cordwent received his medical education at St. George's Hospital and qualified as M.R.C.S. Eng. and L.S.A. in 1840 and in 1841 respectively. He graduated as M.D. at St. Andrews University in 1859 and three years later he was admitted F.R.C.S. Eng. Dr. Cordwent practised in Taunton for many years and was on the honorary staff of the Taunton and Somerset Hospital. He was a former president of the West Somerset Branch of the British Medical Association. About 25 years ago he retired from practice and settled at Milverton. Dr. Cordwent was a life-member of the council of St. Andrews University and also a Fellow of the Chemical Society. He took a great interest in archæological subjects. Dr. Cordwent married a Miss Mathias of Taunton who predeceased him many years ago and he leaves no children. The deceased was much respected in Milverton and the funeral, which took place there on Nov. 16th, was largely attended.

THE WAR IN SOUTH AFRICA.

THE IMPERIAL YEOMANRY FIELD HOSPITAL AND BEARER COMPANY.

BY CHARLES STONHAM, F.R.C.S. ENG.,

CHIEF SURGEON AND OFFICER COMMANDING THE IMPERIAL YEOMANRY FIELD HOSPITAL; SENIOR SURGEON, WESTMINSTER HOSPITAL, ETC.

IN my second letter,[1] sent to you from the Devil's Kantoor, I gave you some account of our marches east and north of Pretoria, to which place we returned from Warm Baths on August 26th, reaching Pretoria at 9.30 A.M. on the 28th after covering a distance of 64 miles. Sending our ambulances on to the Irish Hospital, which is established in the Palace of Justice, we proceeded to camp near the Racecourse, and spent the rest of the day with our five weeks' mails, which were brought into camp by the returning ambulances. We all looked forward to a few days' rest, which had been well earned by the men and transport animals of all units—of the latter, indeed, we had lost many, and those which were still alive were worn out with long marches and scanty rations. The forced march of 64 miles from Warm Baths, coming as it did at the end of a month's hard trekking, had played havoc with the mules; indeed, the field hospital and bearer company combined had to requisition for 70 fresh animals to make up for those dead or quite unfit to move. We were, however, only able to draw 10—60 being the total number allowed for the whole brigade; and when I tell you that all units were in this respect as badly off as ourselves, you will have some idea of the extreme difficulties of transport.

The day after our arrival in Pretoria (August 29th) Major Hale, D.S.O., R.A.M.C., and I went to No. 3 Model School Hospital (commanded by Major R. W. Ford, R.A.M.C.), to which we had lent our detachment for the time being We made all arrangements for the detachment which appeared necessary to us exchanging one or two sick men and providing for the sending home of most of the St John Ambulance men who were time expired We drew a few stores, and changed a couple of our carts so that we should be ready to march at once when orders arrived For these we had not long to wait for at about 12 o'clock we received marching orders for the following day I must say that these orders were received with some regret, as although we were all most anxious to go on yet the whole brigade had confidently looked forward to a little rest and time to refit

---

[1] THE LANCET, Nov. 17th, 1900, p. 1453.

General Hamilton and his division (with the exception of Mahon's brigade) went east on August 29th by train Our brigade was to march On the 30th we struck camp at 7 A M and marched through Pretoria at 9 A M, passing the recently established Yeomanry Branch Hospital in the grounds of Beckett's house at Sunnyside It looked most business like with everything in full swing The orderlies and the nurses came to the railings to see us pass On the opposite side of the road was the Langman Hospital We camped at Donkerhoek at 5 30 P M On Sept 1 we arrived at Balmoral having camped the night before two miles south of Bronkhorst Spruit Our march on this day was by no means pleasant as we had to pass along the road where our animals had perished in such numbers during the storm of the night of July 25th The stench was abominable and nauseating and although we are pretty well used to this kind of thing now, it was so obtrusive that everyone was glad when this part of our journey was over On Sept 3rd we passed through Middelburg and sent our sick to the hospital there We camped at Wonderfontein on the 4th On the 5th as we were inspanning we heard heavy gun fire to the north west of us and after marching on our journey about three miles our artillery and mounted troops with two ambulances under Major Hale were ordered back The rest of the convoy, with the infantry outspanned until late in the afternoon, when the mounted troops beginning to return we moved on and camped after marching for two miles We found that our troops had arrived too late, and that the Boers under Commandant Trichardt, who had attacked a party of Canadians guarding the railway between Pan and Wonderfontein had been beaten off Our ambulances took five wounded men from the camp of the Canadians to Wonderfontein railway station to await a train for Middelburg

On the 6th we joined General French's division at Carolina and rested there till the 9th on which date the division marched into the hills in the direction of Barberton Major Hale and Dr Green with two ambulances followed Mahon's cavalry, the rest going with the main convoy About 10 30 A M our advanced guns engaged the enemy and the convoy parked at the foot of a hill on which two of our guns were placed The guns soon drove the enemy from the opposite hill and after lunch I rode forward to the advanced battery and watched the action for the rest of the afternoon It was most exciting especially at the finish when the mounted Boers broke cover and made up the hill which we had been shelling as hard as they could go under a perfect hail of shell fire from the battery The division now advanced, crossed the hill which we had been shelling, and encamped about 8 P M in the valley, some of the convoy not coming in till the following morning As the convoy was passing over the hill we had just been shelling the Boers sent two shells which passed just over our heads and fell on the other side fortunately without bursting Our casualties in this action were five wounded One man who was shot through the head died in our hospital on the 12th On the next morning we continued our march We were now fairly in the mountains The roads were very bad, and they may be best likened to a dissipated switchback They are broken by numerous drifts over the Komati river, which takes a very winding course through the valley On all sides of us were mountains—indeed, the country was such that had the Boers chosen to hold it at almost any point they might have defied us indefinitely On the 12th we camped at the foot of Roodeloogk an exceedingly steep pass about half a mile long Our guns shelled the Boers from their position here during the morning The remainder of the day and the two days next following were taken up in getting the troops and convoy over the pass—a by no means easy task, as each wagon required a minimum of 24 mules so that constant relays of animals had to be sent down the hill until the last wagon reached the top Our turn to ascend the hill came on the 14th General French had moved on with his cavalry the day before to make a forced march to Barberton, the 4th Cavalry Brigade being left to guard the pass and the next day the rest of us marched to the top of the Devil's Chute, which we descended the following morning The top of the Devil's Chute is about 7500 feet or 8000 feet above sea level and from it there is an extensive and beautiful view of the lower ground surrounded by mountain chains with Barberton about 20 miles distant The Devil's Chute is a winding road about three miles long descending about 2500 feet or 3000 feet to the lower, but still hilly and broken ground Many wagons and animals which had come to grief in the descent bore witness to its difficulties Our mules were now thoroughly done up, we had lost so many that even after inspanning our horses our teams were reduced to six animals, and we only just managed to creep into Barberton on the 17th when we sent our sick to the Boer hospital This march to Barberton will certainly rank as one of the great marches of the campaign, and some idea of its difficulties may be formed when I tell you that the Boers at Barberton—and, indeed, the English residents too—thought that it would be impossible for us to enter the town with our heavy guns and convoy When it was evident to the former that we not only could, but would, enter Barberton, the Boers made preparations to go but General French pushed on and arrived two days before he was expected This caused the Boers to beat a hasty retreat and they left large quantities of stores and over 40 engines I need not dwell upon our stay at Barberton, where we were detained for lack of transport till Oct 2nd We obtained supplies and a small supply of fresh vegetables which were very welcome, as we began to feel the absence of the latter severely—indeed this is one of the chief drawbacks to long marches through an absolutely barren country. Unfortunately there was absolutely no forage to be obtained and our transport animals had to pick up a living as best they could on the veldt Needless to say they died daily A few days before we left a small quantity of forage was issued, and had it not been for this most of the poor animals would have died On Sept 20th the 4th Cavalry Brigade which had been left to guard the pass, marched in followed by the Naval Brigade with their 4 7 gun

On Oct 1st we received orders to march on the following morning We were to proceed by the Devil's Kantoor and we were only to take such wagons as we could find full teams for All the others and the greater bulk of our stores, with the dismounted men, were sent to the station where they would be entrained as soon as the line was repaired We accordingly left two officers and 35 men with seven wagons who camped near the station These were sent on by train and we found them waiting our arrival when we got to Machadodorp On the 2nd Major Hale Dr Green, and I, with 28 men, moved off with 10 carts after passing a most disagreeable night in consequence of the very high wind and perpetual duststorms We marched for 18 miles and camped at the North de Kaap river, the rest of the column going four miles further on Mahon's brigade was now virtually broken up The Imperial Light Horse had been sent on on Oct 1st, and we understood that they went to Pretoria for disbandment M Battery, the ammunition column Lumsden's Horse, and a few details were now all that were left, the others either having been sent away by train or being left at Barberton as a garrison During the night a series of heavy thunderstorms commenced, which lasted practically without intermission, for 18 hours The lightning was extremely vivid and, I regret to say, was fatal to two men in the ammunition column, besides injuring some others and killing some mules Personally I have never experienced such terrible thunderstorms before

On the 3rd we commenced the ascent of the Kantoor by a very bad road, which was excessively steep in parts and wound up the mountain for about seven miles This day we did about four miles in pouring rain accompanied by heavy thunder and lightning The next two days were occupied in getting the wagons up This had to be done in detachments as each wagon required 26 mules The road was exceedingly picturesque and from the top of the Kantoor a magnificent view of the mountains surrounding the low ground in which Barberton lies was obtained On the 6th we reached Godwan River station, and before we proceeded further we had again to cut down our convoy as there was another hill to be ascended at Waterval Onder which, according to accounts we had received, was worse than anything we had yet passed. We left Dr. Green with all the baggage and what little stores we had, two carts, and all the men but eight, to go on to Machadodorp by train. Major Hale and I, with eight men and the rest of the wagons, quite empty except for kits, marched to Nooitgedacht, where I took the opportunity of going over the prisoners' quarters. Our march was through a beautiful valley, and had it not been for the wind and heavy duststorms would have been most enjoyable. On arriving at Waterval Onder about mid-day on the 8th we saw the hill of which we had received such terrible accounts and we were agreeably surprised to find that there was really nothing formidable about it; indeed, in the afternoon we marched up it without difficulty with our usual 10 spans of mules. The following day we reached Machadodorp, where we found the rest of our men and wagons who had preceded us by train. General French's division and some of Buller's troops were here and made a very big camp.

On the 11th we received orders to take part of the field hospital and bearer company and march on the next day with Mahon's brigade, which had been re-formed, the rest of our men being left behind to go to Pretoria by train as soon as possible. Late at night these orders were countermanded from Pretoria, and we were ordered to cross to the north of the line at daybreak and to take over the sick from the field hospital which was to take our place in Mahon's brigade. This, in view of the fact that the Yeomanry, volunteers, colonials, and reservists were being sent down, looked like an early return home, and although, as we had been with General Mahon for three months, we were sorry not to accompany him further, we were all delighted at the prospect before us. We remained at Machadodorp until the 21st, when we entrained for Pretoria, arriving there on the 22nd. During our stay at Machadodorp we had admitted nearly 100 patients, sending them down by sick convoy as opportunity offered.

I have now brought our wanderings up to date and I am afraid some of your readers may be inclined to say, "This is all very well, but he has said nothing about the medical and surgical work which the hospital has done." I have purposely refrained from doing so, as it seems to me injudicious to interlard my letters with professional details. However, when our work as a field hospital and bearer company is definitely terminated I hope to furnish you with such professional details as I think may prove interesting.

Pretoria, Oct. 23rd.

THE BATTLE OF THE CLUBS.

MIDLAND MEDICAL UNION.

THE inaugural meeting of the above union was held at Nottingham on Oct. 10th, Mr. J G. SHEA of Chesterfield being in the chair. There was a representative attendance of members from Nottingham, Derby, Belper, Mansfield, Chesterfield, and the neighbourhood. The Nottingham and District Medical Union were received *en bloc* as members and now constitute the Nottingham branch of the Midland Medical Union. Dr. E. Jepson, President of the Durham Medical Union, had kindly promised to deliver an address but was prevented from being present. His address has been printed and circulated amongst the members.

The following officers were elected:—President: Mr. J G. Shea (Chesterfield). Vice-President: Mr. T. Geraty (Nottingham). Treasurer: Dr. F. R Mutch (Nottingham). Honorary secretaries (*pro tem.*): Dr. E. H Houfton (Shirebrook) and Mr. C. J. Palmer (Mansfield-Woodhouse).

A representative council was also elected and a code of rules was adopted, the principal of which were as follows:—

1. Name of association - "Midland Medical Union"

2. Objects. (*a*) To protect the interests of members of this association in every respect, but more particularly from unfair competition, and from any attempts that may be made to induce or compel medical practitioners to accept insufficient remuneration for professional services; (*b*) to establish and maintain minimum rates of payment for medical contract work in relation to miners and all classes of workmen, members of friendly societies, sick and other clubs, lodges, insurance and other companies and societies.

3. Every registered medical practitioner residing in or near the counties of Nottingham and Derby shall be eligible for membership. Application to be the recognised form and election by a majority of the council.

4 The annual subscription for each member be 5*s*, payable in advance on Oct. 1st. A guarantee fund shall be formed limited to 21*s*. per member, to be called for in case of necessity only.

5 The officers of the union shall be elected annually and consist of president, vice-president, secretaries, treasurers, solicitors, and council. The council to consist of two or more members from each branch, four to form a quorum.

6. The annual meeting shall be held in October, at place to be decided on by council.

8. A special general meeting shall be called by the President at any time upon a requisition signed by six members, such special meeting to consider no other topic than that for which the meeting was called.

9. No member of the union shall oppose any practitioner in any course of action which he may take, with the previously expressed sanction of the council, for the general good of the profession

10. Any member acting, in the opinion of a special meeting called for the purpose, contrary to the laws and regulations of the union shall, upon a majority of at least three-fourths of the members present, be suspended or expelled, and without appeal, from the union

11. A special meeting, called for the purpose of considering the conduct of any member of the union, shall only be convened after 14 days' written notice has been sent to the last known address of each member, and such notice shall state clearly the purpose for which such meeting is convened.

14. No new law shall be adopted, and no existing law be altered or rescinded, except at the annual general meeting or at a special meeting called for the purpose, and 14 days' notice of such proposed alterations, signed by at least three members, shall be sent to every member of the union in the circular convening the meeting.

LOCAL ASSOCIATIONS.

15. That any existing local association of medical practitioners or groups of practitioners in districts where there are such local associations be empowered to form or become a local association of this union, and that each member of such local association having paid to this union the annual subscription for the time being, payable under the foregoing rules, such local association shall be allowed by this union reasonable expenses for carrying on the work of such local association in relation to this union, and also have full authority to direct and control their own local affairs, subject to all questions of special importance being referred to this union and governed by the rules thereof

It is hoped that all medical men in Nottinghamshire, Derbyshire, and the neighbourhood will become members so that something may be done to improve rates of pay for contract work and to deal with other matters of medico-political interest.

The honorary secretaries will be glad to give any information respecting the union and to receive the names of those wishing to become members

THE BIRMINGHAM AND DISTRICT GENERAL MEDICAL PRACTITIONERS' UNION.

In THE LANCET of Dec. 30th, 1899 (p. 1866), we announced the formation of this union. The report of the council of the union to the members for the first year of its existence has just been published. The area with which the union deals is that known as "Greater Birmingham"; it has a radius of some five miles from the centre of the city and it has been divided into 14 medical wards. The members of each ward elect representatives to serve on a central council. Members to the number of 202 have already been enrolled. We gather from the report that owing to the influence of the union five general practitioners have been elected on the council of the Birmingham Medical Institute. Inquiries have been instituted into the abuses of the club system, and though the council of the union do not consider the present time opportune for dealing with the question as a whole, yet they are prepared for action in the case of individual clubs if they are appealed to. We wish the union success, for it is only by organisations of this kind that the abuses affecting the medical profession will ever be remedied.

The officers for the ensuing year are the same as last year, all having been re-elected. They are as follows:—President: Dr. W. E. Parkes. Vice-Presidents: Mr. H. R. Leech and Mr. R. A. Newton. Treasurer: Dr. W. H. Line. Secretaries: Dr. E. D. Kirby, Mr. J. Neal, and Dr. C. Robertson.

THE CORONER AND THE DEATHS OF LUNATICS IN POOR-LAW INSTITUTIONS.

THE following General Order has been addressed by the Local Government Board to the guardians of the poor of the several Poor-law unions in England and Wales, to the boards of management of the several asylum districts formed under the Metropolitan Poor Act, 1867, and to others whom it may concern:—

Whereas it is expedient to provide for the notification of the death of every poor person of unsound mind in any workhouse or in any other building subject to the government of a board of guardians or joint committee of two or more boards of guardians or board of management to the coroner of the district in which such workhouse or other building is situated:

Now therefore we, the Local Government Board, in pursuance of the powers given to us by the statutes in that behalf hereby order as follows:—

Article I —In this Order:

The expression "*Poor law Institution*" means a workhouse a workhouse infirmary or other building subject to the government of a board of guardians or joint committee of two or more boards of guardians, or a district asylum subject to the government of the board of management of an asylum district.

The expression 'Superintending Officer' means in the case of a workhouse, the master, in the case of a workhouse infirmary, the superintendent, or where there is no superintendent the steward in the case of an asylum subject to the government of the board of management of an asylum district the medical superintendent or other head officer and in default of any such persons includes any other officer whose duties comprise the notification to the pauper's relatives of the death of any pauper in a Poor-law institution

The expression "Lunatic' means an idiot or person of unsound mind.

Article II —Within 48 hours after the death of a lunatic in a Poor-law institution notice of such death shall be sent by the superintending officer of such institution to the coroner of the district in which the institution is situated, and such notice shall be accompanied by a statement signed by the medical officer or the medical superintendent or the medical man who attended the lunatic in his last illness and containing the following particulars:—

1 The name sex, and age of the lunatic.
2. Whether married single, or widowed.
3 The apparent cause of death.
4 The time of and any unusual circumstances attending the death, also a description of any injuries known to exist at the time of death or found subsequently on the body of the deceased.
5 The duration of the disease of which the lunatic died.
6 The names and descriptions of any persons present at the death
7 Whether or not mechanical restraint was applied to the deceased within seven days previously to death, with its character and duration if so applied.

Article III —This Order shall come into operation from and after the first day of December, 1900

Given under the seal of office of the Local Government Board this 3rd day of November, 1900

HENRY CHAPLIN, President.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6208 births and 3917 deaths were registered during the week ending Nov 17th The annual rate of mortality in these towns, which had been 17 6 and 16 9 per 1000 in the two preceding weeks, rose again to 17 6 last week In London the death rate was 17 1 per 1000 while it averaged 17 9 in the 32 provincial towns The lowest death rates in these towns were 9 5 in Norwich, 11 9 in Croydon, 12 1 in Cardiff, and 13 4 in West Ham, the highest rates were 20 5 in Liverpool 21 6 in Newcastle 21 9 in Manchester, and 24 8 in Salford The 3917 deaths in these towns included 353 which were referred to the principal zymotic diseases against 485 425, and 356 in the three preceding weeks, of these, 72 resulted from diarrhœa 71 from "fever (principally enteric), 70 from diphtheria, 62 from whooping cough, 47 from measles and 31 from scarlet fever The lowest death rates last week from these diseases occurred in Cardiff, Norwich, Huddersfield, Halifax, and Gateshead and the highest rates in Brighton, Wolverhampton Nottingham, Preston, and Sheffield The greatest mortality from measles occurred in Brighton, from whooping cough in Nottingham Derby Preston, and Sheffield, from 'fever' in Plymouth, Derby, and Sunderland, and from diarrhœa in Swansea Wolverhampton Nottingham and Bolton The mortality from scarlet fever showed no marked excess in any of the 33 large towns The 70 deaths from diphtheria included 32 in London, seven in Leicester, seven in Sheffield five in Liverpool, and four in Portsmouth No fatal case of small pox was registered last week either in London or in any of the 32 large provincial towns, and no case of small pox was under treatment in any of the Metropolitan Asylums hospitals on Saturday last, Nov 17th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2728 against numbers increasing from 1703 to 2702 on the 11 preceding Saturdays, 281 new cases were admitted during the week against 320 336, and 289 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had risen from 164 to 307 in the six preceding weeks, further increased last week to 352 but were 60 below the corrected average The causes of 42, or 1 1 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Bradford, Newcastle, and 14 other smaller towns The largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sheffield

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19 6, 19 6, and 19 2 per 1000 in the three preceding weeks rose again to 19 9 during the week ending Nov 17th, and showed an excess of 2 3 per 1000 over the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 14 9 in Dundee and 17 2 in Leith to 20 5 in Edinburgh and 21 2 in Glasgow The 614 deaths in these towns included 22 which were referred to whooping cough, 16 to diarrhœa, 13 to measles, 11 to diphtheria, seven to "fever," four to scarlet fever, and two to small pox In all, 75 deaths resulted from these principal zymotic diseases, against 77 and 62 in the two preceding weeks These 75 deaths were equal to an annual rate of 2 4 per 1000, which was 0 8 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of whooping cough which had increased from 13 to 22 in the five preceding weeks, were again 22 last week, and included 17 in Glasgow, two in Dundee, and two in Paisley The deaths from diarrhœa, which had decreased from 53 to 17 in the six preceding weeks, further declined last week to 16, of which seven occurred in Glasgow, four in Dundee, and three in Aberdeen The fatal cases of measles, which had been eight and five in the two preceding weeks rose again to 13 last week, and included eight in Edinburgh and four in Aberdeen The deaths from diphtheria which had been seven in each of the two preceding weeks, increased last week to 11, of which five were registered in Glasgow, three in Edinburgh, and two in Perth The seven fatal cases of "fever" corresponded with the number in the preceding week, and included six in Glasgow The deaths from scarlet fever, which had declined from eight to four in the three preceding weeks, were again four last week, and included two in Glasgow and two in Paisley The two fatal cases of small pox were both recorded in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had increased from 98 to 150 in the six preceding weeks, further rose last week to 163, and were 31 above the number in the corresponding period of last year The causes of 21, or more than 3 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN.

The death rate in Dublin, which had been 20 0, 21 9, and 22 5 per 1000 in the three preceding weeks further rose to 26 0 during the week ending Nov 17th During the past four weeks the death rate in the city has averaged 22 6 per 1000, the rate during the same period being 16 7 in London and 17 3 in Edinburgh The 174 deaths belonging to Dublin registered during the week under notice were 23 above the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 13 and 11 in the two preceding weeks, of these, three resulted from "fever three from diarrhœa two from whooping cough one from measles one from scarlet fever, and one from diphtheria These 11 deaths were equal to an annual rate of 1 6 per 1000 the zymotic death rate during the same period being 1 2 in London and 2 6 in Edinburgh The deaths referred to different forms of "fever, which had been three and four in the two preceding weeks declined again to three last week The fatal cases of diarrhœa which had been five and six in the two preceding weeks declined last week to three The 174 deaths in Dublin last week included 25 of infants under one year of age and 61 of persons aged upwards of 60 years, the deaths of infants showed a decline, while those of elderly persons considerably exceeded the number in the preceding week Eight inquest cases and six deaths from violence were registered and 44 or more than one-fourth, of the deaths occurred in public institutions The causes of seven, or more than 4 per cent, of the deaths in the city last week were not certified

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon A. G. Delmege is granted the honorary rank of Deputy Inspector-General of Hospitals.

The following appointments are notified:—Fleet Surgeon A. McKinlay to the *Camperdown*. Staff Surgeons: R. F. Bowie to the *Hone*; J. H. Thomas to the *Cormorant* for Gibraltar Hospital; and G. T. Broatch to the *Devastation*. Surgeons: J. M. G. Swainson to the *Terrible*; A. J. Hewitt to the *Trafalgar*; E. Folliott to the *Assaye*; and R. St. G. S. Bond to the *Highflyer*.

IMPERIAL YEOMANRY.

Private Lewis Johnstone Weatherbe to be Medical Officer with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Raglan Wykeham Barnes retires on retired pay. Lieutenant-Colonel John J. Falvey retires on retired pay.

Captain W. A. Ward joins the Home District for duty in London. Major J. H. Nicolas is selected for duty in the Southern District at Gosport. Lieutenant Carr is detailed as medical officer for the Royal Artillery Brigade Division at the new Ewshot Hut Barracks.

INDIA AND THE INDIAN MEDICAL SERVICES.

Colonel Davis, C.B., D.S.O., is appointed Principal Medical Officer, British Contingent, China Expeditionary Forces, vice Colonel Bookey, invalided.

VOLUNTEER CORPS.

Royal Engineers: 1st Cheshire: Surgeon-Lieutenant J. F. Blake-Campbell resigns his commission. *Rifle*: 1st Volunteer Battalion the Buffs (East Kent Regiment): Charles Mason Atkinson to be Surgeon-Lieutenant. 1st Volunteer Battalion the Hampshire Regiment: Douglas Lawson Thomson to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Supernumerary Surgeon-Lieutenant J. W. Smith to be Surgeon-Lieutenant on the Establishment.

TRANSVAAL WAR NOTES.

Civil Surgeon J. B. Christopherson has returned to England.

Lieutenant W. Jagger, R.A.M.C., and Civil Surgeons W. L. Wainwright, L. V. Cargill, and W. C. Allan are returning home in the *Assaye*, which left for England on Nov. 17th. The following invalids are also on board:—Major T. Archer, R.A.M.C., Lieutenant F. S. Walker, R.A.M.C., and Civil Surgeon D. V. M. Adams.

Civil Surgeons R. Ward, A. Breslin, C. Gibbs, H. J. Scharlieb, and W. W. Wooliscroft left in the *Yorkshire* for England on Nov. 15th.

The hospital ship *Princess of Wales* sailed for England on Nov. 13th with 171 sick and wounded on board. She is due at Southampton on Dec. 5th or 6th.

The *Dilwara* arrived at Southampton on Nov. 20th with the following invalid officers on board:—Civil Surgeons F. D. Boyd, A. H. Watt, G. L. Chiene, J. Miller, J. McFarlane, G. S. Stoker, Coleman, and J. C. Ponder; Dressers A. C. Balfour, H. V. Fletcher, H. Gribben, W. H. Nutt, G. Paulin, Edwards, Thomson, McIlwain, and Stewart; Civil Surgeons Enrys and Roberts, of the Welsh Hospital; and Sir W. Thomson, of the Irish Hospital.

Major C. E. Faunce, R.A.M.C., Captain F. J. Wade-Brown, Civil Surgeons H. Bayliss, N. B. Harman, and H. B. Maunsell have been discharged from hospital to duty.

Sir William Thomson and the members of the staff of Lord Iveagh's Irish Hospital arrived in Dublin on Wednesday morning, Nov. 21st, and were received with warmhearted enthusiasm.

ARMY REORGANISATION AND REFORMS.

There is naturally a considerable amount of curiosity as to what may be the nature and extent of the coming army reform in which the Army Medical Service will, of course, share. But it is a question which concerns the whole army and not merely the medical branch of it, and is a big business. The changes will require to be far-reaching and radical if they are to satisfy the public mind in its present temper. Mr. Brodrick, the new Secretary of State for War, made a judicious and well-balanced speech at Godalming on Nov. 6th. He has already had much War Office experience and as he will be intimately associated with Lord Roberts, who will take up his appointment at the Horse Guards fresh from the South African campaign, to say nothing of all his previous war experience, we may expect that the reforms and reorganisation will at any rate be run on safe and practical lines. Sir Michael Hicks-Beach's recent speech at Bristol from the Treasury point of view struck us as a logical vindication of his position and a trenchant criticism and reply to much of what has been put forward from the purely military side. He had no difficulty in showing that our military system requires a change in several directions in order to bring it abreast of the requirements of the Empire and those of modern warfare and that something more than the expenditure of money is necessary.

THE WAR IN SOUTH AFRICA.

We may direct attention to the interesting articles by Mr. Charles Stonham appearing in THE LANCET as illustrating the great topographical difficulties of a campaign in South Africa. From his descriptions it will be seen that our troops with their hospitals and hospital establishments have had to make most laborious marches and to fight physical geography as well as the enemy. The events in South Africa carry us back to the long and successful defiance of the French arms in La Vendée and, more recently, to the formidable nature of the task undertaken by the Austrians in their occupation of Bosnia and Herzegovina.

THE CITY IMPERIAL VOLUNTEERS

The members of the Volunteer Ambulance School of Instruction received Surgeon-Major R. R. Sleman, who went to the front in medical charge of the C.I.V., on Saturday last at their headquarters. In reply to an address of welcome he remarked that the result of inoculation for enteric fever had proved very satisfactory, for there were 50 per cent. more recoveries among men so treated than among the others. Surgeon-Major Sleman, A.M.R., C.I.V., and also Surgeon-Captain E. W. St. V. Ryan, A.M.R., C.I.V., will be entertained at dinner this (Friday) evening at the Café Florence by the staff of the school.

THE HEALTH OF THE TROOPS IN SOUTH AFRICA

The troops in South Africa are on the whole healthy. There is, nevertheless, as might be expected under the circumstances, a good deal of disease incidental to camp life and campaigning present among them. The amount of enteric fever, which may be said to be endemic in South Africa, is very much less than it was, but if the prevalence of that fever comports itself in the way that it does in India we may expect more of it during the hot season and after the rains.

Correspondence.

"Audi alteram partem."

THE CORONER AND THE DEATHS OF LUNATICS IN POOR-LAW INSTITUTIONS: A VALUABLE REFORM.

To the Editors of THE LANCET.

SIRS,—Some years ago I drew the attention of the Lunacy Commissioners to the fact that no provision was made for notifying to the coroner the death of any lunatic in Poor-law institutions, and in December, 1899, I again called attention to the matter. In reply I was informed that a workhouse, hospital, or infirmary of a union under the management of the guardians did not come within the definition of "an institution for lunatics" under the Lunacy Acts. In consequence, I brought the matter before the Coroners' Society, and by direction communicated with the Home Office, pointing out the desirability of such deaths being reported to the coroner, as is done in all asylums and houses licensed for the reception of lunatics.

The Local Government Board have now issued a General Order, of which I enclose a copy. By it you will see that the death of any person of unsound mind under the care of any

Poor-law board must be reported to the coroner in like manner as lunatics, and that the word "lunatic" means "an idiot or person of unsound mind." The particulars to be furnished to the coroner are similar to those given by the authorities at asylums or licensed houses.

This consummation of our efforts is highly satisfactory to the coroners themselves and, I should think, to the medical profession and the public generally. At times rumours are heard of ill-treatment of lunatics in Poor-law institutions but formerly, as the coroner had no notice of deaths he knew nothing as to particulars until too late for him to interfere. Now, however, coroners will be cognisant of all such deaths if the Order is properly carried out and he can make further inquiry and order an inquest if necessary before the body is buried. By the operation of this Order the Poor-law institutions which retain lunatics even temporarily will have to fall into line with those admirable institutions for the reception of lunatics under the county or borough authorities and in private licensed houses where strict supervision is given. Another public advantage is that friends or relatives having an alleged grievance can ask the coroner to hold an inquest, and though this may throw additional work on the coroner I cannot think that any one of us will shirk responsibility, for if the charge is unfounded the credit of the institutions will be established and if sustained a remedy may be suggested. As this is a matter of interest to the medical profession I venture to ask space for the publication of this letter and of the Order (or so much of it as you may think necessary).—I am, Sirs, yours faithfully,

A. BRAXTON HICKS,

Honorary Secretary of the Coroners' Society of England and Wales.

Lupus-street, Nov. 19th, 1900.

*** (The Order will be found printed on p. 1528 of this issue.—ED. L.

"APPENDICITIS."

To the Editors of THE LANCET.

SIRS,—In addition to Sir Samuel Wilks's letter in your impression of Nov. 3rd I can affirm that in 1859 Mr. James Long (brother of the eminent classic George), in his course of lectures on surgery in Liverpool not only included diseases of the cæcum and inflammatio appendicis, but objected to the terms "cæcitis" and "appendicitis" as hybrid, slipshod words, and used the terms "typhlitis" and "perityphlitis" and commended their use.

I was Mr. Long's private pupil at the time, when he had been 22 years' lecturer on anatomy and eight on surgery, and I know he was in favour of early surgical "interference," or rather assistance. I am, Sirs, yours faithfully,

Brook-street, W., Nov. 20th, 1900. TOM BIRD.

THE LATE WILLIAM ANDERSON, F.R.C.S.

To the Editors of THE LANCET.

SIRS,—As an old St. Thomas's man who has had the advantage and privilege of association with the late Mr. Anderson, first as a pupil and afterwards as a friend, I venture to trespass upon your space to invite old St. Thomas's men who have had a similar happy experience of his teaching and generous sympathy to show their appreciation of it by cooperating with me in perpetuating his memory in the hospital where he has been such a conspicuous figure as teacher and friend. Any attempt at laudatory commendation would be superfluous. His life is so well known to St. Thomas's men that I feel certain there are many who will gladly avail themselves of any opportunity that may offer to secure such recognition of his services as would be acceptable to the hospital and gratifying to his friends. I shall be glad to help in any way and will readily respond to anyone who may wish to join in this effort.

I am, Sirs, yours faithfully,

W. GIBSON BOTT.

37, Kennington Park-road, S.E., Nov. 20th, 1900.

"THE TREATMENT OF SPRAINS AND OF SOME FRACTURES."

To the Editors of THE LANCET.

SIRS,—I have read Mr. A. H. Tubby's address on sprains and fractures with much interest, and, though it contains nothing particularly novel, it is well that good rules of practice should be insisted on. I quite agree with Mr. Tubby that the only proper time for the use of cold applications in cases of sprain is immediately after the accident; but unfortunately the surgeon does not usually see these cases in the first quarter of an hour, and later warm applications are better. But I am surprised that Mr. Tubby entirely ignores the application of adhesive plaster to sprains, and I think he will find that strips of the American indiarubber plaster, carefully applied, give better results than a bandage with cotton-wool beneath it. The use of plaster-of-Paris can seldom be required in cases of sprain and has the disadvantage of causing stiffness which requires a good deal of massage, or possibly forcible movement, for its relief.

It is, however, the second part of the address which is most important, and I am glad to find the treatment of injuries about the elbow without splints inculcated. I have practised this method for many years, and in THE LANCET of Jan. 12th, 1889, I published a clinical lecture in which I say: "I believe that in all cases of fracture of the lower end of the humerus the elbow should be well bent. I include, of course, cases of separation of the lower epiphysis, and I like to bring the forearm thoroughly up so as to put the hand to the opposite shoulder, and then I feel confident that the fragments will fall into the best position." I have seen such terrible results from treating these fractures with rectangular splints, and particularly splints made of flat boards, so that the elbow and arm are tightly compressed when the inevitable swelling occurs, that I venture to emphasise Mr. Tubby's excellent teaching and to [illegible] the credit of it to Mr. Jonathan Hutchinson, from whom I learnt it.

I am disappointed not to learn Mr. Tubby's method of treating fracture of the olecranon, which he apparently ignores. In 1883 I read a paper before the Surgical Section of the British Medical Association at Liverpool, urging that in cases of fractured olecranon the elbow should be bent to a right angle and the forearm carried in an ordinary sling. I have always treated these cases in this way with the best results and I have seen disastrous consequences from keeping the limb straight, to say nothing of the discomfort to the patient during the treatment. I may add that I have never had occasion to wire a fractured olecranon.

I am, Sirs, yours faithfully,

Cavendish-square, W., Nov. 18th, 1900. CHRISTOPHER HEATH.

"THE IMPROPER USE OF ASYLUMS FOR THE INSANE."

To the Editors of THE LANCET.

SIRS,—Could you help in a matter that calls for a thorough change of plan? Lunatic asylums are built for the insane; delirium tremens is a passing madness only, and is recoverable from by the rigid withdrawal of the exciting cause. Clearly the Act never contemplated the treatment of such afflicted persons as lunatics. Among the poor, if the boards of guardians cannot take such cases in and put them under proper restraint, we, certifying magistrates, are constrained to send these poor people to asylums. They get rapidly well and are yet prejudiced as to future employment by the fact that they have been lately under asylum treatment, and so the drink craze is bound to resume its sway, recrudescent as it is from idleness and low spirits and lack of food. Thus the mode of cure makes sure of the renewal of the disease: surely a sad irony on modern methods.

I am, Sirs, yours faithfully,

GEORGE H. R. DABBS, M.D. Aberd.

Shanklin, I.W., Nov. 16th, 1900.

"THE WEDGE OPERATION FOR ENTROPION AND TRICHIASIS."

To the Editors of THE LANCET.

SIRS,—With regard to an article under the above heading appearing in THE LANCET of Nov. 3rd, 1900 (p. 1280), I wish to call your attention to the fact that a modification of Snellen's operation has been constantly advocated and practised by Mr. W. E. Cant, of the British Ophthalmic Hospital in Jerusalem, for many years past, differing in no essential detail from that described under the above heading. Personally I have only used it in 300 or 400 cases, but Mr. Cant has used it in a large number (probably 7000) of cases. It is also used by men working in Palestine who have seen the modified Snellen's operation done in

Jerusalem by him. If the incision is continued through the conjunctiva no harm results and a very good result is got, but this should only be done in healthy lids. Sutures to bring the skin together need never be used and in almost all cases a linear scar results which is often indiscernible in two or three years. The cases in which the operation as above described is contra-indicated are those in which much skin has already been removed by native practitioners or quacks (generally with scissors). In such there may be failure to close the lids without strong effort, and the cornea is exposed during sleep. In these cases the operation tends to exaggerate this defect. For these I believe Van Millingen's operation to be by far the best available, because the latter lengthens the lid slightly. Only last summer I saw many cases in the north of Palestine where failure to close the lids after quack operations had resulted in partial, if not complete, xerosis corneæ, and others in which failure to close the lids during sleep would probably result in this.—I am, Sirs, yours faithfully,

J. CROPPER, M.A., M.B., B.C. Cantab.,
Late of Acre, Palestine.
Chepstow, Nov. 7th, 1900.

⁂ Surgeon-Major Herbert's method of operation has been practised by him for many years. The cases refer to the year 1895. We regret that we did not make this clear.—ED. L.

"NECROPSIES IN MEDICO-LEGAL CASES."

To the Editors of THE LANCET.

SIRS,—I have read with interest the leading article in THE LANCET of Nov. 10th (p. 1357) in which you refer to the importance of making a complete post-mortem examination in medico-legal cases. With your remarks I most fully concur, and my object in writing this letter is to accentuate a point which arises in connexion with the last case referred to in your article—viz., the importance of examining the cervical vertebræ. Fracture or dislocation of the neck as a result of violence is by no means so rare as might be supposed and these conditions not infrequently exist without any external signs of injury or, indeed, any indication that death has resulted from other than natural causes, and are therefore easily overlooked unless the vertebræ are subjected to careful examination.

Two instances illustrating this fact have recently come under my notice—one in which a man drawing a barrow slipped and the contents, weighing about 1 cwt., fell upon the back of his head and shoulders, and the other the case of a man who was found dead at the bottom of a short flight of stairs. In neither instance was there any external sign of injury; in both there were pathological conditions of the heart which *might* have accounted for death, but in both the examination of the neck in the manner I am about to describe, which should form part of the routine procedure in all post-mortem examinations, led to the discovery of the true cause of death. The procedure, which is well known, consists in extending the mesial incision on the anterior aspect of the body to a point immediately below the symphysis menti and then reflecting the skin for a short distance on either side of the neck. The knife is then passed up close to the lower jaw and the attachments of the tongue to the floor of the mouth are divided. The tip of the tongue is hooked down by the left forefinger until it can be firmly grasped and pulled downwards, while with the right hand the knife is passed boldly backwards, dividing the soft palate and tissues of the posterior pharyngeal wall. The whole of the soft structures in the neck, including the soft palate, tonsils, and fauces, are now easily brought down into view and one or two cuts with the knife serve to separate them completely from their position in front of the cervical vertebræ.

The advantages of the above procedure being followed in every case are two-fold: first, it is the only way in which the condition of the upper air-passages, pharynx, and tonsils, can be properly examined; and, secondly, I venture to maintain that in no other way can the presence of any fracture or dislocation of the cervical vertebræ be clearly made out. The first proposition everyone will agree with, although my experience is that this method of examination is frequently neglected or imperfectly carried out, with the result that such causes of death as œdema glottidis, or accidental suffocation from choking, more especially in young infants, are often overlooked. With reference to the second proposition, everyone who has made the attempt must be aware of the difficulty of speaking definitely as to the presence or absence of fracture the cervical vertebræ from mere manipulation of the head and neck, more especially when rigor mortis is present; in fact, it is impossible, as a rule, to give a definite opinion upon the point. If, however, the cervical vertebræ have been exposed in the manner described, then by placing one hand on their anterior surfaces and moving the head with the other hand, or, better still, placing the finger in the foramen magnum after removal of the skull-cap and brain, any abnormality can be detected with ease and certainty.

My excuse for writing upon a matter which may appear trivial is your article, and the fact that, notwithstanding the well-known rule that all post-mortem examinations in cases of sudden or violent death should be full and complete, the structures and organs of the neck are frequently totally neglected or only imperfectly examined; whereas, if the parts were exposed in the manner indicated as a matter of routine in all post-mortem examinations such an oversight as the one mentioned by you could never take place, while not a few apparently mysterious deaths would be satisfactorily explained. A point also of considerable practical importance is that no greater disfigurement of a body is occasioned than in a less complete examination.

I am, Sirs, yours faithfully,
HARVEY LITTLEJOHN.
Surgeon's Hall, Edinburgh, Nov. 19th, 1900.

"THE MICRO-ORGANISMS OF VACCINE MATERIALS."

To the Editors of THE LANCET.

SIRS,—I have read with interest in THE LANCET of Nov. 17th (p. 1414) an article by Dr. J. B. Buist on the subject of vaccine organisms, in which he refers to certain observations made by him with my assistance some 15 years ago. I wish it to be generally understood that although my name has been freely made use of in his book (1885) and also in his present paper above cited, I entirely dissociate myself from the conclusions at which he appears to have arrived. To say that a *spore* is the *contagium vivum* of vaccinia is simply a confession of defeat in his very noble effort to clear up an awkward pathological problem. Every bacteriologist should know that a spore—i.e., the immature ovum of any *contagium vivum*—is not to be looked upon as a definite cause of disease. It is only as one follows the life-history of such a spore through its subsequent developments that one is able to assign to it its pathogenetic rôle, and it is only matter of regret that in his paper Dr. Buist has neglected to take this sequence into his consideration. His paper is of so much interest and importance that one must venture to re-assert the well-known dictum that *like produces like*. That a torula should give birth to micrococci, that they in turn should be spores of bacilli and may be fat or lean according to nutrition and environment, and in sequence give birth to one or other type of micro-organism, is a theory not supported by exact research and one so chimerical as to make exact research appear at a disadvantage. Having taken part in Dr. Buist's research to the extent he mentions, and having absolutely declined to associate myself in his book (*op. cit.*, 1885), I think it is now my duty to dissociate myself from the views expressed in his paper in your last issue.

I have no doubt that an artificial nutrient medium for the development of vaccine lymph will soon be introduced; and if it can be standardised, as so many drugs have lately been standardised, for medicinal use, so much the better. There ought to be little trouble in this matter, and the result should strengthen the hands of the Local Government Board in insisting upon vaccination of a uniform type, and supported by irrefragable scientific evidence of unquestioned authority. I must leave the further discussion of this matter to the specialists who can scarcely fail to realise its importance at the present juncture.

I am, Sirs, yours faithfully,
ARTHUR W. HARE, M.B., F.R.C.S. Edin.
Newquay, Cornwall, Nov. 19th, 1900.

"THE QUESTION OF THE COMMUNION CUP."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 13th reference is made in an annotation to "intinction" as a sanitary substitute for individual or separate communion cups; the latter, suggested by a correspondent in the same issue, are dismissed rather *summarily as impracticable.* *Regarding the revival of the* former method of celebrating the Lord's Supper I agree that the sanitary reasons for the change are both patent and cogent, although it is not unlikely that there will arise many ecclesiastical or dogmatic objections to the change from many quarters. But the reason for advocating intinction that THE LANCET gives—namely, that individual communion cups are not practicable—is valid or not according to whether the subject is viewed from the sacerdotal or sanitary standpoint

If THE LANCET means that individual communion cups are impracticable in the Church of England because of certain doctrines, or because of the ritual, "high" or "low," that may obtain, then I have no protestation to make; the advocates of this sanitary reform do not urge any body of the Christian Church to relinquish any beliefs that it considers vital and dear to its spiritual serenity or moral conduct, and holding which it believes would be jeopardised by substituting individual for the commonly-used communion cups. But if THE LANCET means that individual cups are not *feasible from a purely sanitary point of view,* then it is very mistaken, permit me to urge. Furthermore, though admittedly a "modern" innovation, that has not made it necessarily difficult of adaptation—here in America at least; nor has any church found that it introduced "complications into a rite" or rendered the service of the ordinance less "dignified, solemn, and reverent."

Individual communion cups have come increasingly into use during the past six years, and I have yet to learn of one church that, having adopted them, would under any consideration use the single or several cups again. Hundreds of churches are constantly demonstrating the individual cups to be not only practicable but practical—clean, safe, expedient, and reverent to use. I have recently canvassed to find out about how many are now using these cups. It is difficult to learn of all, but I have at this time collected 732 churches, distributed throughout the United States (in all but three or four States) and in all of the principal denominations. The majority of these churches are in the eastern and middle western states, and in the Baptist, Congregational, and Presbyterian churches, the Reformed, Lutheran, and Methodist Episcopal churches being next in order, the Protestant Episcopal (sister to the Church of England) and Universalist churches having separate cups being fewest in number. I have reason to believe that there are approximately 800 churches now using the cups throughout Christendom, about four times as many as in 1897, and representing nearly half a million communicants—evidence of wholesome substantial progress.

Whatever the method of avoiding the unclean, unsanitary single chalice, it is gratifying to note the increased interest and moral courage being shown in desiring the proper union in performance as well as in promise of cleanliness with godliness at the Lord's table as well as at our home table.

I am, Sirs, yours faithfully,
HOWARD S. ANDERS.
Philadelphia, Nov. 9th, 1900.

THE ROYAL ARMY MEDICAL CORPS "AS SEEN FROM WITHIN" BY A VOLUNTEER SURGEON-CAPTAIN TEMPORARILY ATTACHED R.A.M.C.

To the Editors of THE LANCET.

SIRS,—I have had the privilege of six months' service with the Royal Army Medical Corps, both at home (Aldershot and Cowshott) and in Cape Town and Pretoria and neighbourhood during the present Transvaal War, and after 16 years as a private practitioner may be allowed to express my opinion on this important establishment of Her Majesty's army. The work done by this corps can only take a first place, in my opinion, among the other branches of the service. In point of fact, I doubt whether any other corps can excel in the work effectively achieved by them during this dire war.

As a plain volunteer officer who has been temporarily attached to the army and has worked hand-in-hand with the military surgeon and has studied his daily routine I claim the right to give expression to my views in the matter of the corps' usefulness, competency, or otherwise. I consider the medical service a model of what is expected in any modern army and doubt whether any other army could show better results, especially after strict trial, as has been the case with us in the present struggle. Several improvements might advantageously be forthcoming and will in all probability occur sooner or later, but up to the present, as far as I can find, no definite action in this important matter has taken effect.

My suggestions are these and may meet with the approval of many military and civil surgeons:—1. Retain the military titles, which are necessary for obvious reasons. 2. In *military matters* have undoubtedly *military discipline*: for example, a superior officer should certainly have power to order his junior officer to attend a certain case or cases at any time or place or to give any order for any other medical purpose he chooses; but (3) in *medical matters* there should be substituted *medical etiquette.* I deny the right of any medical officer senior to the officer in attendance to interfere with the care and treatment of any case under the latter's charge. Every medical officer in the army should be responsible to Government and to Government alone for the care of his sick and wounded and if found incompetent should be discharged the service. 4. There should be less "writing up" of diet sheets and report sheets; this takes up a considerable time of the army surgeon's work. 5. As to requisitioning for instruments and medicines, especially the former, the present practice is perfectly absurd: it causes unnecessary delay and is often responsible for the safety of a patient's existence. I hold that the protection of human life is one of the most sacred duties and any system which militates against this must be radically wrong.

As a cure to existing evils I would suggest:—1. Relieve the army medical officer of the vast amount of useless filling in of diet sheets which takes up his time to an extent so as to interfere greatly with his usefulness in his medical and surgical wards. 2. Arrange for a commission composed of prominent medical men who have had experience of professional work in time of war, and of officers of the Royal Army Medical Corps, who are not sufficiently long in the service to be influenced by "red-tapeism," and draw out some such scheme as here proposed and the army in the future will even be better doctored than at present.

I am, Sirs, yours faithfully,
FRANCIS WILLIAM GRANT, M.D., B.Sc. Edin.,
Surgeon-Captain, 1st Banff Volunteer Artillery,
Captain (temporary) R.A.M.C.
Elgin, N.B., Nov. 12th, 1900.

MEMORIAL TO THE LATE MR. G. J. SYMONS, F.R.S.

To the Editors of THE LANCET.

SIRS,—On May 31st a meeting was held at the rooms of the Royal Meteorological Society to consider the question of a memorial to the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation. It was resolved unanimously that the memorial should take the form of a gold medal to be awarded from time to time by the Council of the Royal Meteorological Society for distinguished work in connexion with meteorological science. An executive committee was appointed to take the necessary steps to raise a fund for that purpose. We have now much pleasure in stating that their appeal has been very heartily responded to, not only by meteorologists, engineers, and representatives of other branches of science and industry, but also by personal friends and admirers of the late Mr. Symons in all classes. The committee have decided to keep the list open until the end of January, 1901, in order to allow all who have in any way benefited by Mr Symons's advice and assistance to contribute to the Memorial Fund.

We are, Sirs, yours faithfully,
C. THEODORE WILLIAMS, M.D., Treasurer.
R. MELDOLA, F.R.S., } Secretaries.
WM. MARRIOTT. }

"SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—I take the liberty to send you under separate cover a copy of the *South London Press* of Nov. 3rd, 1900, in which you will find an account of the action taken by the Lambeth Vestry against the South London Electric Supply Corporation, for creating a nuisance by burning of street refuse, the complaint being: (1) the smoke; (2) the dust and ashes blown into the gardens and houses; and (3) the stench arising from the combustion of the refuse.

The decision of the magistrate was that, on the Electric Supply Corporation giving an undertaking not to burn street refuse in future in their furnaces or to permit any effluvia to be emitted from their chimney, the judgment would be postponed *sine die*. The corporation having given this undertaking no fine was imposed, but should the nuisance be repeated the proceedings can always be re-opened. I may mention that the vestry of Lambeth summoned the corporation after having received a memorial signed by 10 householders, as demanded by Section 21 of the Public Health (London) Act. I think this result is very satisfactory, and if the communities in other parishes will take a lesson from this we may soon succeed in improving the air we breathe in London.

I am, Sirs, yours faithfully,
Nov. 3rd, 1900. L. R.

THE VESTRY OF CAMBERWELL AND THE ANTITOXIN TREATMENT OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—The late vestry of Camberwell, shortly before its death, published and circulated a leaflet, signed by the bacteriologist, concerning diphtheria and its treatment by antitoxin. After stating that antitoxin cures 99 per cent. of cases of diphtheria and that a single dose protects a healthy person from the disease for a month and making some other similar statements for which there does not seem sufficient warrant, he finishes up this remarkable document as follows: "About 70 of the doctors in the parish are using the remedy and having suspicious throats examined. If all would do the same there would not be one death where there are 20 now."

We must all admire zeal in the discharge of his duties on the part of a public official and of a public body, but we might expect the zeal to be tempered by discretion. The paragraph which I have quoted adds nothing to the value of the document and appears to me to be a gratuitous insult to the practitioners of the parish. I cannot imagine by what means this gentleman can discover whether his fellow practitioners are or are not using antitoxin. And finally he accuses them of causing the deaths of 19 out of every 20 cases of diphtheria. Personally I protest in the strongest manner against this language and consider that an apology should be offered to these gentlemen by the bacteriologist and the leaflets withdrawn from circulation.

I am, Sirs, yours faithfully,
Nov. 17th, 1900. CAMBERWELL.

*** The circular in question is before us. Like our correspondent we respect the zeal that has led to its issue, but we do not think it happily worded. It protests too much. Yet the good that it will do outweighs in our eyes the objections that may be taken to some of the statements on the ground of exaggeration.—ED. L.

A VISIT TO ROBBEN ISLAND.

(FROM A CORRESPONDENT.)

Robben Island Asylum.

ONE does not go to a war to get holidays, and yet I have managed to secure two, both of which were very enjoyable. On the first occasion I was escorted down a gold-mine at Johannesburg, and on the second I was conducted by Dr. Gregory, the medical officer of health of Cape Colony, to see the well-known asylum for the Cape lepers My thanks are due, too, to Mr. Piers, the lay commissioner in charge of the island, to Dr. Black and to Dr. Mitchell, who showed me everything within their various domains. The early history of leprosy in South Africa is vague, but there are native traditions which tend to the belief that the scourge existed amongst the Hottentots before the white man discovered the Cape. It was, perhaps, introduced later among the Dutch settlers from the Dutch East Indies, whence their servants were procured. About the year 1817 there were so many lepers that the first asylum in South Africa was opened by the British who had been virtual rulers of Cape Colony since 1806. The spot selected, called "Heaven on Earth," was in the Caledon mountains, not very far from Cape Town, and it is interesting to note that this district still supplies a very large percentage of lepers.

In 1845 the patients were transferred from Hemel-en-Aarde to Robben Island, which takes its name from an old Dutch word for the seal. Whales must have been frequent neighbours of the island, for their remains are still used as palings and boundary marks there. The island, history tells us, was used as a quarantine station in 1803 and perhaps earlier; then criminal lunatics were confined there, and now there are 270 lunatics, 600 lepers, and 120 convicts. It was not till 1892 that the Leprosy Repression Act for compulsory segregation was brought in. The Ministers of that day feared that there would be opposition, but the friends of the lepers made no sign. The island is conveniently situated, being two miles long and half a mile wide, and is distant six miles from Cape Town. Yet this stretch of sea, which takes less than an hour to cross in a steam-tug, is considered by the Kaffirs a great drawback. Moreover, they complain of the loneliness of the island, forgetting that any compulsory leper asylum must be equally irksome to the inmates. The statement that the island is barren and ugly may be true of some months of the year but it is certainly not the case in September, when the fields are rich with lovely arum lilies growing as weeds. However that may be, the sentimentalists in the House of Assembly have carried the day and a promise has been given to the lepers that they shall have an asylum built for them on the mainland. As a consequence of this no improvements are being carried out in the leper quarters, which is, perhaps, the chief reason why they look neglected and forlorn. The numbers include 360 males and 240 females, mostly Kaffirs, with a few separate huts for the Dutch. There are now no inmates of English birth. These figures include the lepers of the Orange River Colony who were prevented by the war from being moved to a new asylum which had been built for them at Bloemfontein. The Kaffir male and female compounds are separated by high barbed fences and palings, which are not always sufficient to prevent illicit flirtations among the lepers who greatly resent being deprived of the society of the other sex. The island is rich in churches and Sunday services for the lepers are held in English, Dutch, and Kaffir. The sanitary arrangements seem to be as perfect as could be expected, but there are two or three obvious blots which might be remedied. The institutions on the island are not directly under the control of the sanitary department of the colony—i.e., the medical officer of health—though they may be theoretically so. Then there is no regular supervision of either lepers or lunatics by independent experts, so that there is no one beyond the medical officers on the island to decide whether a patient should be released or detained indefinitely. Perhaps the evil which appealed most to me was that I saw the non-leprous children of leper women living with dozens of lepers with no attempt made to isolate them from the danger of their surroundings and no care taken of their education. This has been strongly reported upon by the medical superintendent in his annual statements and ought at once to be ended. The case could easily be met by putting a schoolmistress in a cottage on the island where a kindergarten could be started and where the leper mothers might be allowed under strict regulations to see their children every week. Much good work is being done by the medical men in charge of the lepers. Photographs are taken of all of them, microscopical and bacteriological work is carried on, and there are every year some 60 post-mortem examinations made. Two-thirds of the lepers are of the anæsthetic type and they usually die from pulmonary tuberculosis, while the remaining third are either nodular or mixed lepers, and they die from kidney and liver infection. If compulsory asylums are justifiable it is obvious that cases of nodular leprosy and mixed leprosy must be isolated; but are anæsthetic patients equally dangerous to the community? Dr. Black and Dr. Kolle systematically examined the nasal discharge of the anæsthetic cases with the result that leprous bacilli were found in the noses of several old-standing cases which were apparently quite quiescent. This more accurate and modern method of examination may cause several cases to be re-considered which had been thought to be entirely arrested.

Lunatic Asylums.

Money is much wanted to supply separate accommodation for the lunatics, for at present criminals, paupers, and paying patients all want sorting badly. In one airing court I saw a European dangerous patient with the native lunatics, because the other Europeans were afraid to have him with them. Among other acts of violence he had succeeded lately in fracturing the thigh of the head attendant during a struggle. Last year a female patient while out walking with two nurses and some other patients suddenly broke loose from them and sprang over the rocks into the sea. One of the boatmen swam out through a heavy sea and brought the patient to a rock, but she was swept out of his grasp by the surf and drowned. I understand this is a very exceptional occurrence.

Emjanyana Leper Asylum.

This is the only other leper establishment in Cape Colony, and, with the exception of one in Pretoria, the only other in South Africa. The numbers vary from 250 to 300, the two sexes being divided pretty equally. Here again, there are confined a few non-leprous children, who have either been admitted with their leper mothers or have been born in the wards of women admitted while in a state of pregnancy. Two years ago 12 male lepers and four female lepers effected their escape in spite of a guard of the Cape Mounted Rifles. On the day after the escape the dormitories were carefully searched and a number of sticks, stones, knives, and pieces of sharpened iron were found secreted in the bedding. The ringleaders confessed that they had intended to use force to obtain their escape. The lepers are satisfied with their diet and medical treatment, but they believe that they are wrongfully detained after being cured and they abhor the strict separation of the sexes. Lately there has been no outbreak among the patients.

Cape Town, September

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Plague and Cholera in India.

THE increase in the plague mortality throughout India which I have had to record during the past few weeks seems temporarily arrested, only 2123 deaths having occurred during the past week in India against 2136 in the previous seven days. There were fewer deaths in Calcutta (88 against 101) and in the Bombay district (1142 against 1215). In Mysore, however, the number of deaths continues to rise, the returns showing 765 deaths this week compared with 696 last week, the total for the outbreak being 28,734 cases and 23,186 deaths. Two cases of plague have occurred in the Royal Artillery at Bangalore, and a third case is reported as suspicious. The disease is rapidly making headway in Poona, 95 deaths having occurred yesterday (Oct. 10th). Two cases have occurred in the Cantonment amongst persons inoculated last year, but amongst the 7688 inoculated this year not one case has so far occurred. Plague is reported to have reappeared in the Hischispur district of the Punjab but only a few cases have up to the present been noted. Plague has within the last few days broken out in epidemic form at Patna. In this crowded city therefore a much more serious development than occurred before (February) may be expected. This early recurrence within eight months is particularly interesting because it is similar in time to the first recurrence of plague in Poona in 1897, whereas Bombay, Calcutta, and other places have for the most part had an interval of about a year.

The health of Calcutta since the floods in the third week of September has been very bad. Although the mortality is declining it is still very high. The increase of deaths is almost confined to the suburban or added areas of the city, the districts to the east and south of the city. These areas are undrained, low-lying, and naturally swampy, and were most affected by the rains. During the past fortnight while the normal mortality would be 812 the deaths have been 1872. Plague is apparently on the increase. Cholera, diarrhœa, dysentery, and the direct effects of exposure explain the chief excess since the heavy rains.

The health of Bombay, which has been so bad for many months, continues bad. The general mortality is slowly declining, but 947 deaths were registered last week against an average of less than 600. Plague deaths were numbered at 84, but the increase in the new cases and deaths during the past few days suggests that a further development is in progress. The figures to-day are about on a level with those of the same period last autumn.

Cholera still continues in some of the cantonments. A small outbreak is reported amongst the 4th Hussars at Secunderabad and amongst some native regiments at Meean Meer and Sialkot. In Kashmir this disease is still very virulent. Up to Oct. 7th there were 2157 deaths and in addition Srinagar had 821 deaths. There is no sign of the visitation falling off. In the Punjab also it is raging extensively, as for the week ending Sept. 22nd 914 cases were returned and the total cases (48,675) and deaths (25,115) have formed the heaviest cholera rôle since 1892.

Oct. 11th.

The Famine and Plague.—The Increase of Deaths from Phthisis in Bombay City.

In nearly every part of India the harvest promises to be a bumper one. The exceptions are the Deccan, Guzerat, and the Carnatic, where rain has been very deficient. The numbers on famine relief have now dropped to about 1,250 000 and nearly all these are in the Bombay Presidency, and chiefly in Guzerat. The relief works are closed in Madras, the North-west Provinces, and the Punjab.

Plague throughout India remains about the same. The chief places at present suffering are Poona, Nasik, Mysore, Belgaum, and Bangalore. At Poona the outbreak seems to have attained its height and has begun receding. In Mysore city the cases are still numerous. In Bombay city there is the same steady return of from 12 to 20 cases a day. The mortality of the city still keeps very high, having been 834 last week, as compared with the five years' mean of 678. In Calcutta is to be noticed a sudden absence of the return of plague deaths. There has been a steady improvement of late in the general mortality and a decline in the numbers returned of plague deaths, but the sudden cessation of all plague deaths suggests that some change of policy in the returns has been inaugurated. Whereas previously we heard of suspicious deaths these also are not now published, so it can only be inferred that some order has gone forth that even the most highly suspicious deaths are not to be returned as plague. With the experience of the past two years one can hardly believe that this represents the true state of the city. Highly suspicious deaths we are told continue to occur, but living cases have latterly not come under observation. If this absence in the return of plague deaths be a change of policy such as was adopted in 1898, it is, to say the least, very misleading.

In a Government resolution recently published it is observed that there has been a remarkable increase since plague first appeared in Bombay in the number of patients suffering from phthisis at the large hospital. Whereas in 1896 there were 212 patients suffering from phthisis, in 1897 the numbers rose to 405, the following year they rose to 530, while in 1899 no less than 607 were admitted.

The municipal statistics of death registration during these plague years show similarly a large and steady increase in the deaths from phthisis and other pulmonary diseases. The health officer naturally attributes the increase to plague in some of its forms, but the surgeon-general considers that this explanation is inapplicable to the hospital cases and has arrived at the conclusion that there has been actually a great rise in the mortality from phthisis in Bombay city during recent years. The increase of the hospital figures is so remarkable (the cases and deaths from phthisis having nearly trebled) that one cannot but think that plague has had immense influence. It has been observed that phthisical subjects who survive an attack of plague show rapid decline afterwards. It is probable, therefore, that many of these phthisical subjects at the hospital may have had plague before admission. It is also extremely probable that many of them actually died from plague. The municipal returns of deaths from "other pulmonary diseases" covers a multitude of possible diseases, as the registration of anything like the correct cause of death in the majority of cases is extremely problematical. The inference of the health officer is perfectly legitimate and it is also probable that the whole of the excess mortality in Bombay city since plague first appeared may, with the exception of deaths due to certain other well-known and recognised epidemic diseases, be put down to plague.

Oct. 31st.

CARDIFF INFIRMARY.—At a meeting of the executive committee of the Cardiff Infirmary held on Nov. 14th it was stated that the adverse balance of the institution now amounted to £11,035.

BIRMINGHAM.

(From our own Correspondent.)

The University of Birmingham.

The founders of a new institution accept an enormous weight of responsibility and a vast amount of work in the pursuit of their object. This is clearly illustrated in the labour and energy involved in promoting the new University of Birmingham. The arrangement of the many new subjects of study involve much thought and careful consideration, while the multiplicity of details in working and the arrangements tax the time and the strength of all the chief promoters and their allies. The dean of the medical faculty (Professor B. C. A. Windle) has been indefatigable in looking after the interests of the school of medicine and ever ready in seeking to maintain its efficiency and high standard. Of late he has been actively engaged in the important task of arranging for the examinations for medical degrees to which practitioners of a certain standard will be admitted. Already a large number of practitioners have expressed a desire to submit themselves to the examinations, and it is expected that the number will be largely increased. This examination offers a healthy stimulus to revive the knowledge of former years by the additions of modern methods in order that the coveted degree may be obtained. Some of the classes show a goodly proportion of quali[illegible] men anxious to equip themselves for the ordeal. The dean is willing to give any information to applicants for particulars as to classes, text-books, and all details.

City Health Returns.

At this season of the year the returns of the Health Committee show much fluctuation, but unfortunately they exhibit a high relative increase of infectious diseases. For the week ending Nov. 10th the record showed that scarlet fever was increasing and typhoid fever was decreasing. Last week this order was reversed, scarlet fever having decreased from 80 to 60 cases and typhoid fever having increased from 25 to 38 cases. The epidemic is not so severe as in some seasons, for during the past week, of the total number of deaths registered only three had reference to scarlet fever and six to typhoid fever. Measles is credited with four deaths, the general death-rate being 18 3 per 1000. 484 cases of scarlet fever were under treatment at the hospital—a large number even in a large population. The Widal blood-test in cases of typhoid fever is recommended by the Health Committee, who have arranged to bear all expense in providing glass tubes and outfits for the purpose, in addition to the tests being conducted in the laboratory of the University.

South African Experience.

The Pathological and Clinical Section of the Birmingham Branch of the British Medical Association is ever ready through its active secretaries to excite interest in the work of the section. A meeting has been arranged for Nov. 30th at which Mr. Frederick Treves has kindly consented to give an address on Notes from a Field Hospital in South Africa. Birmingham has contributed well to the work done so nobly in this quarter—Mr. J. F. Hall-Edwards and Mr. C. A. Leedham-Green having been actively engaged in important duties. It is expected that a large audience will be present to give a hearty welcome to Mr. Treves.

Superstition still Existing.

A curious instance of superstition occurred lately in one of the suburbs of Birmingham. Two men were engaged in dragging the canal for a child's body. A small loaf of bread was placed in the water within a few yards from the men and it was stated that as soon as the loaf turned round they would be near the body. It is an old superstition in the Midlands that if a dead body is in the water and a loaf into which some quicksilver has been inserted is allowed to float about, it will stop over the spot where the body lies. It is hardly necessary to point out how entirely fallacious such an idea must be, and yet there are to be found those in this enlightened age who believe in the practice. It is, of course, well known that obstructions in running streams cause eddies, and these collect floating substances—light matters passing rapidly down on the surface; but a weighted object like a loaf of bread with quicksilver inside would sink nearly below the surface and would be caught by the undercurrent of the eddy caused by the corpse and so remain stationary. This possibly is the matter-of-fact explanation of an apparently occult phenomenon.

Nov. 20th.

LIVERPOOL.

(From our own Correspondent.)

Hospital Saturday Fund.

The annual meeting of the subscribers to the Hospital Saturday Fund was held recently under the presidency of the Lord Mayor (Mr. A. Crosthwaite). The treasurer's statement showed the amount collected to have been £7103 16*s.* 10*d.*, an increase of £83 1*s.* 1*d.* over the year 1899. Notwithstanding that the day appointed for the ladies' street collection was most unfavourable for the work, the result had been very satisfactory. Since 1890 the fund had increased by £3062 4*s.* 2*d.*, the return of that year being £4041 12*s.* 8*d.*, while the expenses, which were 8 per cent. in the former period now amounted to about 5 per cent. There were now in use 1695 boxes, 865 cards, and 131 firms who adopted their own system—an increase over 1899 of 67 boxes, 38 cards, and 16 firms using their own method—a total of 121 new collections commenced during the year. One feature of this branch of the report, to which the treasurer called special attention, was the increase in the number of firms working their own collections, and he would strongly recommend the adoption of that system where possible. During the year 122 notes of admissions to the various hospitals had been supplied through the office. The Hospital Saturday Fund was now represented upon the committees of all the hospitals to which contributions were made, and the representatives were unanimous in their testimony as to the very close attention given in any case of complaint or suggestion made to them by the committee. It is pleasing to find that the representatives of the fund on the various hospital committees speak in terms of praise both of the good work accomplished by the medical staffs and nurses in the several institutions and of the economical yet efficient manner in which these institutions are conducted.

The Central Hospital, Liscard.

A highly successful bazaar in aid of the funds for building the new central hospital at Liscard was concluded on Nov. 19th, the total amount realised being £5800 The committee of the hospital have much cause for congratulation, as the amount desired was only £4000.

Liverpool School of Tropical Medicine.

Dr. R. Fielding-Ould, Dr. C. Balfour Stewart, and Dr. A. S. F. Grünbaum have been appointed assistant lecturers in the Liverpool School of Tropical Medicine. These gentlemen have afforded much assistance to the school in many different ways, and it was felt by the committee that it would be of great advantage to the school to have their coöperation as official members of the teaching staff. In view of the return of the second malarial expedition from West Africa the following resolution was carried unanimously at the recent meeting of the committee :—

> That the best thanks of the Liverpool School of Tropical Medicine are due to Dr. Annett, Dr. Dutton, and Dr. Elliot for their valuable services in West Africa whilst members of the second malarial expedition of the school; and, further, that the committee of the school desire heartily to congratulate the expedition on its safe return from its labours.

At the same meeting a resolution was passed thanking his Excellency Dr. J. Paes Carvalho, the Governor of the State of Pará, for the magnificent reception which he extended to the yellow fever expedition of the school on its arrival from Cuba and for the public-spirited manner in which he had interested himself in the success of the expedition.

Nov. 20th.

IRELAND.

(From our own Correspondents.)

Port Medical Superintendent of Dublin.

At a meeting of the Port Sanitary Authority of Dublin held in the City Hall on Nov. 13th, Mr. Daniel Bergin presiding, it was decided to appoint Sir Charles Cameron to the office of Port Medical Superintendent at a salary of £50 a year.

Royal College of Surgeons in Ireland.

His Excellency the Lord Lieutenant, Lord Iveagh, and many other distinguished guests have already accepted invitations to be present at the dinner to be given on Nov. 24th by the Royal College of Surgeons in Ireland to welcome Sir William Thomson and the other members of the staff of the Irish Hospital home from South Africa. A telegram has been received from Sir William Thomson stating that the members of the staff reached Southampton on Nov. 20th, and would arrive in Dublin by the London and North-Western Railway Company's steamer *Cambria* at 7.30 A.M. on Nov. 21st

Poor-law Medical Appointments in co. Down.

Dr Charles O'Neill has been appointed medical superintendent officer of health for the Holywood district of co Down. The district extends from the outskirts of Belfast, embracing Castlereagh, to Holywood, and the duties of the post are to report once a month to the Belfast Guardians, while once a month the officer will receive a report from each of the dispensary medical officers in the district He will consult with these medical officers if any question of sanitary matters arises, and for this work the guardians propose to give him £8 per annum, he to pay his own travelling expenses. The other district is from Whiteabbey, embracing Ligoniel, to the Black Mountain at Dunmurry, and the guardians propose to pay the medical superintendent officer of health for this large area £10 per annum. In former times Dr. Seaton Reid did all the work and was paid £50 per annum; now the guardians make two appointments, for which they pay £8 and £10 respectively, which is but a miserable pittance for the work to be done. Of course, owing to the extension of the area of Belfast, part of the district formerly under the charge of the guardians has been taken into the city of Belfast, but still the remuneration proposed to be paid by the guardians to their two new health officers is wretchedly small and inadequate It only shows to what Poor-law medical appointments in Ireland are coming.

The Housing of the Working-classes in Belfast.

Dr. Henry O'Neill, J.P., who went as a delegate from the City Council of Belfast to the late Sanitary Institute conference in London and the Tenth International Congress of Hygiene and Demography in Paris, has presented a report on "The Housing of the Working-classes" to the Public Health Committee of Belfast. Dr. O'Neill gives an account of discussions at the London conference on "Unhealthy Areas and Displacement of Town Populations," on "Improved Houses for Town-dwellers," and on "Improved Means of Communication." He also gives details of reports presented to the Paris Congress on "Industrial and Professional Hygiene: Insanitary Houses." Dr. O'Neill thinks that by a judicious application of the Housing of the Working-classes Act, 1890, and its amending Acts a very great improvement might be effected in more than one district of Belfast, and he puts forward a series of most useful recommendations for improving the hygiene of houses, streets, &c He makes a practical suggestion (plan being given) for a scheme to improve one of the most densely populated districts of old Belfast, an area bounded by King-street, Divis-street, Barrack-street, and College-square North, as well as for an open space at the junction of the Crumlin and Old Park-roads. Taking the year 1899, he says that of the population of Belfast—350,000 as calculated by the Registrar General—2117 persons died from preventable diseases—that is, because of disobedience to the ordinary laws of health. Dr. O'Neill has, as a result of great trouble and unceasing energy, now presented to the Belfast Public Health Committee three important reports on (1) "The Housing of the Working-classes"; (2) "The Inspection of Meat-supply"; and (3) "The Inspection of Milk-supply of Cities and Towns, and how the Supply of Meat and Milk is Controlled by Municipal Corporations so as to enable the citizens to obtain meat and pure milk." With the Public Health Committee, therefore, further action as to these reports now rests.

Londonderry Infirmary.

The medical appointments under the new scheme for the regulation of this institution were made on Nov. 15th In former times there was one extern medical attendant (physician and surgeon combined), now there are to be two surgeons and two physicians and an intern house surgeon. Mr. Joseph Byrne, M R C.P., F R C S. Irel, and Mr. J. E. Miller, M.B., B Ch. Dub, have been appointed the new surgeons, and Mr. Thomas MacLaughlin, L.R C.P, L R C S. Edin., and Mr. Walter Bernard, F.R.C.P Irel., M R.C S. Eng, were elected as physicians. Mr. J. G. Cooke, M.B, B Ch. Dub., was reappointed resident medical officer. There is a strong feeling that in all the county infirmaries of Ireland it is far too narrow a policy to have only one extern medical officer There should be at least two, one a physician and the other a surgeon Londonderry is to be congratulated on having led the van in a very necessary reform, and on having broken through the narrow policy of past ages.

Donegal Lunatic Asylum.

At the monthly meeting of the governors of this institution, held in Letterkenny on Nov. 15th it was reported that the number of male patients had increased from 365 to 388 since the staff was last increased, and on the female side from 185 to 206. Both sides of the house were overcrowded It is proposed that there should be an increase of two male and two female attendants.

A Herbalist's Plaster

An inquest was held by the Belfast city coroner on Nov. 15th, in reference to the death of a female, aged 35 years. It would appear that the woman suffered from lupus of the nose. She had been operated on at the Royal Victoria Hospital, but the sore had not healed and a herbalist on Oct. 25th put a plaster on the nose, for which he was paid 5*s* by the woman's husband. The woman had to go to bed on Oct 26th and died on Nov. 2nd (no medical man having seen her) She had previously complained of headache and "pains in her inside." The post-mortem evidence was to the effect that the nose was in a state of acute inflammation, but that the cause of death was heart disease, death being accelerated by the depression produced by the pain of the arsenical plaster. The jury found that the woman died from heart disease, and that her death was accelerated by the application of an arsenical plaster to the nose by the herbalist. The depositions are to be sent to the Attorney-General, with whom the further conduct of the case rests

Disinfecting Machines.

At a meeting of the Lurgan Board of Guardians on Nov. 15th Mr J. M Moore reported on the testing by a committee of a disinfecting machine used by them as well as in Portadown. On the outside of the machine there was a gauge which was supposed to indicate the temperature within. On heating the apparatus to the usual height three different tests were made by placing a thermometer inside the machine and comparing it with the outside gauge. A thermometer was wrapped up inside a blanket and when the outside gauge indicated a temperature of 450° F. the thermometer registered only 112°, showing an error of 338° on the part of the machine. In the other tests the thermometer was placed in the machine uncovered with the result that errors of 232° and 207° were proved. As it is necessary to get a temperature of 300° to destroy germs the machine was thus both defective and deceptive, for people who had their clothing passed through it believed the articles to be properly disinfected, whereas such was not the case. A charge of from £1 to 30*s*. had been made to every person using the machine in Lurgan and in Portadown, and the guardians and the public had been deceived The machine had been relied upon by the workhouse, by the sanitary bodies of Lurgan and Portadown, and by three rural councils. It was advised that a permanent disinfecting chamber should be erected and that the makers of the machine (which cost £200) should send an expert to test it in the presence of the committee

Belfast Medical School.

It is satisfactory to know that despite the falling off in the number of students at other schools this year there is little change at Belfast. At the Queen's College there is a slight decrease, 189 as against 200 last year, while at the Royal Victoria Hospital there is an increase, 155 as against 147 of session 1899-1900.

Royal Victoria Hospital, Belfast.

Mrs W. J Pirrie, who with her husband, the Right Hon. W J Pirrie D L has done so much to raise the necessary funds for the building of the new Jubilee Memorial Hospital in Belfast, is collecting a sum of money to perpetuate the memory of the late Professor J Cuming A tablet is to be placed in the ward of the new hospital called after Professor Cuming inscribed with the names of contributors of five guineas and upwards In March last the amount subscribed for this object amounted to £7000, and Mrs. Pirrie now makes a further appeal, so that when she closes the list on Dec. 15th she may have realised a total sum of £10,000.

Assault on a Medical Man.

Mr. M. M. Sheedy of Kilmallock, in the discharge of his duty as a guardian, directed the attention of the board of guardians of the Kilmallock Union to the fact that some of the inmates had come from other union districts. As the result of an investigation five men were discharged from the house. One of them, named McNamara, went to Mr. Sheedy's residence one evening lately and abused him. Mr. Sheedy ordered him out and he accordingly left, but marched up and down outside still indulging in abusive language. After a time he approached one of the windows and shattered it, doing damage to the amount of £1. Mr. Sheedy rushed out and confronted McNamara who told him that it was he who had broken the window, that he would do it again, and that he would "do" for him (Mr. Sheedy) when he came out of prison. McNamara followed up his threats by seizing Mr. Sheedy and endeavouring to throw him down, but fortunately the procedure was reversed, as Mr. Sheedy managed to grapple with his assailant and to hold him till the police arrived. In due course McNamara was brought before the magistrates and even then his attitude was so threatening that it was found necessar to place a constable on each side of him. He was sentenced to a month's imprisonment with hard labour for being drunk and disorderly. For breaking the window and using threatening language he was ordered to find bail himself in £20 and two sureties of £10 each, or in default to be imprisoned for three months, to take effect on the expiration of the first sentence. Mr. Sheedy's plucky action and the exemplary sentence of the magistrates ought to serve to teach the rowdy element in workhouses that assaulting guardians and destroying property is an amusement which cannot be indulged in with impunity.

Nov. 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Drinking-water Question.

THE question of the quality of the drinking-water supplied to Paris is always coming to the fore and I have many times brought the subject before the notice of your readers. Every year as the hot weather comes round the matter is discussed with fresh interest. The water engineers argue that the supply of drinking-water far exceeds the quantity necessary for the population, while the hygienic authorities reply first of all that the water is not as pure as the engineers maintain because it does not come from a source which is free from danger of contamination, and secondly, that even if it were pure a great part of the supply is taken up by lifts and for flushing closets and the like, because it is supplied at such a pressure that it can be used for such purposes without the company needing to have recourse to the pumps which are necessary for the water of the Seine to be so used. These arguments take place every year and meantime the question is no nearer solution. The only real remedy—namely, that of a double and separate supply, one of drinking-water and the other of water for working purposes supplied at a proper pressure—is never applied. The engineers persist in their idea of increasing the supply of so called drinking-water, and to this end they are always taking up new sources of supply and constructing new filtering-beds. However, all the principal sources of supply in the neighbourhood of Paris are already taken up; new ones have to be sought at a greater distance and consequently at a greater expense, and owing to the increase in the number of houses these sources are liable to pollution from contamination of the gathering grounds. As for filtering-beds it becomes more and more evident that but little trust can be placed in them. So it comes to pass that typhoid fever is far from having disappeared from Paris as it has from Vienna, and as it would have disappeared from Paris if that city were supplied exclusively with good drinking-water—for the sums which have been expended to this end are enormous and quite enough for the purpose. During the month of October the weekly number of cases of typhoid fever, so far from diminishing, have been from 70 to 90, with a mean of seven deaths. In the suburbs, especially at Saint Denis and Gennevilliers, the number of deaths from typhoid fever has been three times as great as during the corresponding period of 1898. The water engineers give their stock answer: they say that the inhabitants of Gennevilliers, for instance, persist in drinking the water of the Seine in spite of all prohibition and in spite of there being plenty of drinking-fountains. As for bacilli, they are ubiquitous. They are found in mineral waters, in spring water, and on fruit and vegetables, while on the skin of one peach as many as 250,000 have been found. Another explanation which the engineers give as to the presence of contaminated waters in the town reservoirs is that the river Vanne, which supplies most of the capital, is fouled at its source, and they bring forward as a proof of this argument that the town of Sens, which is higher up the stream than Paris and derives its water from the river, is as much stricken with typhoid fever as is the capital itself.

At a recent meeting of the Council of Hygiene there was a lively discussion on this subject. M. Henriot remarked that as a matter of fact the town of Sens had been free from typhoid fever this year at the very time when Paris was most affected by this disease. The sources of the Vanne could not therefore be to blame and it was evident that the pollution occurred between Sens and Paris and most likely in the Paris reservoirs themselves. The chief engineer, M. Bechmann, who had at the beginning of the summer declared that not a drop of Seine water would be given to the inhabitants of Paris to drink, said that Seine water had been mixed with drinking-water in the mains when the water-supply looked like failing altogether, but this had only happened once. The results, however, are sufficiently serious, for typhoid fever, which in 1898 gave rise in Paris to 346 cases with 67 deaths, was the cause in 1899 and the first half of 1900 of 3553 cases and 600 deaths. One of the daily papers started an inquiry and arrived at the following startling results:—It is unfortunately true, even in addition to the probable pollution of the water of the Vanne, that the Charonne reservoir has constantly supplied unwholesome water to the Parisians with the full knowledge and acquiescence of the engineers. The Charonne reservoir is divided into two parts, one of them containing ordinary Seine water and the other containing water derived from the filtering beds at Ivry. These filtering beds, which have been constructed quite recently in opposition to the opinions of the committees of hygiene at great cost, are composed of successive layers of gravel gradually becoming finer (*système Puech*); in the opinion of the inventor himself they act merely as strainers, and do not really purify the water, because the water as it issues from the filters still retains from 60 to 70 per cent. of its organic matter and about 5 per cent. of its microbes. The intake of this water at Ivry is in one of the dirtiest portions of the Seine, near factories which discharge waste water into the river and near the outlets of sewers of suburban parishes. Under these circumstances the water as it comes from the filters cannot really be regarded as fit for drinking, and it is this water which after arriving at the Charonne reservoir has been conveyed to the reservoir at Ménilmontant and has been there mixed with the wholesome water of the Dhuys. This proceeding has been going on for four months. It was just then that typhoid fever attained its maximum in Paris. When the engineers saw that the matter was discovered they discontinued mixing the water and typhoid fever immediately declined with the precision exhibited by a laboratory experiment, for in 12 days afterwards the mortality fell from 18 deaths per week, a rate at which it had remained for a considerable time, to seven deaths per week. The Council of Hygiene has been much exercised by these revelations, and after hearing a careful report by M. Le Roy des Barres protested against the imperfect purification to which the river water which had been distributed for human consumption had been submitted. Resolutions were also unanimously passed by the council declaring the following to be urgent requisites:—(1) effective and permanent supervision by the Council of Hygiene over the collection, conveyance, and distribution of water intended for human consumption in the Department of the Seine; (2) maintenance of a sufficient space free from contamination round the intakes or gathering grounds; (3) constant inspection of the original sources of the water, so that any water of doubtful quality may be shut off; (4) protection of the water from contamination during the whole of its transit; (5) eventual purification of the water either by filtration or otherwise and resumption of the experiments on sterilisation on a large scale; and (6) immediate separation in Paris of the water intended for human consumption from that intended for other miscellaneous or trade purposes.

Small-pox in Paris.

At the present time there is a recrudescence of small-pox in Paris. As a rule there are always some few cases of this disease existing, but only a very few, for vaccination is practically obligatory throughout France. Such cases as do occur, therefore, are found almost entirely in foreigners, and it was therefore to be expected that the enormous influx of foreigners into France for the Exhibition would result in an increase of the cases of small pox. Such is the case. During the year 1899 the deaths from small-pox in Paris numbered four. The Exhibition was opened in April, 1900, and from Jan. 1st to the end of May there were 15 deaths from small-pox, while from June 1st up to the closing of the Exhibition (Nov. 11th) there were exactly 100, of which 14 occurred during the week Oct. 28th to Nov. 3rd, a week during which the Exhibition was particularly well attended. Two arrondissements were specially affected, the one being Grenelle, where most of the foreigners employed in the Exhibition were lodged, and the other being the eighteenth, close to the Aubervilliers Hospital, which is reserved for cases of small-pox.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Examination for the Degree of M.D.

IN Germany the possession of the degree of M.D. does not carry with it any legal authorisation to practise medicine. In order that a practitioner may be *legally* qualified he must pass the State examination, and for the purpose of avoiding the anomaly that a duly appointed Doctor of Medicine might be unqualified in the eye of the law it was last year decided that Germans should not be allowed to graduate as M.D. until they had passed the State examination. The conditions of examination for the degree of M.D. have hitherto differed very much in the various universities, but by a decree of the Federal Council they have now been made uniform. The candidate has to write a "dissertation" on a scientific subject, and this dissertation must be approved by the medical faculty and printed at the expense of the candidate. There is a great difference between the oral examination for Germans and that for foreigners, the former being not much more than a mere formality, because the candidates have already passed the difficult State examination. German candidates have, in fact, only to present themselves for a short "colloquium" with the dean and two members of the medical faculty, and in this respect foreigners, if duly qualified to practise in Germany, are regarded as Germans. Foreigners who have not passed the State examination, and who are therefore not qualified to practise in Germany, have to pass the "examen rigorosum" before a commission consisting of the dean and seven members of the medical faculty. There are two oral examinations, one theoretical and one practical The subjects of the theoretical examination are anatomy, physiology, pathology, and hygiene; those of the practical examination are clinical medicine, surgery, and gynaecology with obstetrics. The practical examination has to take place at a hospital, and the candidate must examine several patients. In the theoretical examination the time allotted to each candidate is one hour in anatomy and physiology respectively and half an hour in pathology and hygiene. The classifying distinctions of successful candidates are "rite," "cum laude," "magna cum laude," and "summa cum laude," the last distinction being granted only by the unanimous vote of the whole medical faculty. Unsuccessful candidates may present themselves a second time after the lapse of six months. Foreigners desiring to graduate as M.D. have to produce certificates showing (1) that their general education is in accordance with the regulations in force in their respective countries, and if such regulations do not exist they have to satisfy the examiners that their education is approximately equal to that given at German schools; (2) that they have attended a course of instruction lasting from four to five years at a proper medical school abroad or at a German university; and (3) that they have been registered for at least one semester as students at the medical faculty of the university where they desire to graduate as M.D. Exemptions from the above rules may be granted under special circumstances. The principal feature of the new regulations is the obvious rendering of the examination more difficult for foreigners.

Medical Graduation at Various Universities.

In the year 1899 the number of men who became qualified to practise was 1364. It was remarkable that many more candidates passed at Munich (179) than at Berlin (141) The number of medical students at Munich increases from year to year, so that the clinics, laboratories, &c., of this university are altogether overcrowded. German students have the right of changing from one university to another during their curriculum, and many of them do so several times. As Munich is a very pleasant place, owing to the "gemüthlichkeit" (affability) of the townspeople, its situation in the immediate neighbourhood of the Alps, and last, but not least, the wide-spread renown of the Munich beer, a great many medical students have a preference for Munich University. The number of medical students in Munich was 1165 in the summer of 1899, whilst in Berlin only 1093 matriculated. As to the teaching staff, that of the Munich Medical Faculty consists of only 62 professors and *privat-docenten*, as compared with 142 at Berlin. The number of degrees conferred at Wurzburg was 139, being, therefore, not much less than at Berlin, although only 566 medical students were registered there. The Berlin State examination being regarded as the most difficult one in Germany it would seem that a good many students leave Berlin one or two semesters before the end of their curriculum and settle at another university in order to pass the examination there. The number of medical degrees conferred at the other universities were as follows:—111 at Halle, 95 at Leipsic, 89 at Kiel, 72 at Bonn, 65 at Freiburg, 64 at Breslau, 69 at Erlangen, 44 at Strassburg, 44 at Greifswald, 43 at Jena, 40 at Gottingen, 37 at Konigsberg, 36 at Tubingen, 33 at Marburg, 29 at Giessen, 28 at Heidelberg, and 16 at Rostock. 21 foreigners became qualified, of whom three were Americans and one was an Englishman.

Serum Treatment of Malaria.

An important communication concerning malaria has been made by Dr. Sander of Berlin in the *Deutsche Medicinische Wochenschrift*. He has received a letter from Dr. Kuhn, chief medical officer to the South-West African field force, to the effect that he (Dr. Kuhn) had succeeded in curing malaria by injections of serum The serum is obtained from horses which have contracted the so-called "sterbe" disease. By injections of this serum malaria becomes altered from a chronic relapsing disease to an acute one, curable in from two to six weeks; immunity is also obtained. After the injection slight fever of a more continued character generally appears, but no local reaction takes place. 60 natives immunised by Dr. Kuhn in 1899 did not take the disease in the malarial season of that year, whilst numerous others who had not been immunised fell ill but were cured by the injection. Dr. Kuhn being on his way home more detailed information will be received very soon.

Plague at Bremen.

A case of plague occurred at Bremen a fortnight ago, the patient being a sailor on board a steamer which had come from Brazil, Bacteriological examination showed that his illness was plague. He had been for three days in the town and had been in communication with a great many people. The other members of the crew of the steamer were conveyed to the hospital and kept under observation, but as no other case has since happened they have now been discharged. The patient himself died in three days. The report of a fresh case of plague at Hamburg was unfounded. A sailor suspected of having this disease was found to be suffering from simple sore-throat and was discharged from the hospital in a few days.

ROME

(FROM OUR OWN CORRESPONDENT.)

The Agitation against Foreign Practitioners.

THOSE agitating for the exclusion from practice in Italy of medical men holding only foreign diplomas have evidently no intention of allowing the question to drop. At the meeting lately held in Rome by the delegates of the Ordini di Medici the subject was again brought up by Dr. Santini, who, after recounting what had already been done in regard to it, recommended that the different branches of the Association should bring their influence to bear upon the deputies of their respective districts so as to facilitate and to hasten the presentation to the new Parliament of the projected law which was about to be submitted to the last Legislature when the dissolution took place. This Bill, it will be remembered, in its final form proposed not only to restrict the list of foreign medical men admitted to those holding diplomas of countries granting reciprocity to Italy, but further to permit those who might then still remain to practise amongst persons of their own nationality only. This latter restriction would seriously affect the British practitioner in Italy by cutting off his American *clientèle* and possibly also that from British colonies. If the Bill be allowed to pass in this form the effect will be to exclude from practice all foreigners who do not possess an Italian degree, since no country, so far as I am aware, grants precisely the same amount and kind of privilege as this Bill proposes to accord to foreign practitioners. True, certain prominent members of the profession here promise that the Bill will be modified in this particular before it is passed in such a way as to meet the liberal offer of Great Britain to put into force for Italy Part II. of the Medical Act of 1886, which will secure to Italians properly qualified full rights of practice in Great Britain. Whether this concession will be made remains to be seen; meanwhile the suspense amongst foreign medical men of all nationalities, who realise that within a short time they and their families may be deprived of the means of livelihood, is naturally very great. The remedy, it has been said, lies in their own hands—let them take an Italian degree. To the younger men this is doubtless a possible solution of the difficulty, although even to them the task of preparing for and passing examinations conducted in Italian is sufficiently formidable and the hardship would be great. But that the older men should be required to go through such an ordeal is not reasonable or just, and yet it is upon them, for obvious reasons, that the loss entailed by the prohibition to practise would fall most heavily.

Typhoid Fever and the Consumption of Raw Vegetables.

Professor Gualdi, chief of the Bureau of Hygiene of Rome, who has given much attention to the study of typhoid fever as it occurs in large cities and who intends shortly to publish a paper on the subject, has observed a close connexion between its prevalence and the consumption of raw vegetables, the seasonal curve of typhoid fever corresponding closely to that indicating the quantity of such vegetables sold throughout the different months of the year. Apart from the occurrence of local infections due to accidental pollution of water-supply or milk-supply, the contamination of either of the latter cannot satisfactorily explain the distribution of cases in the city of Rome, whereas it is readily accounted for on the hypothesis that these cases arise in connexion with the consumption of raw vegetables which is so extensive amongst the lower classes there. At Padua a careful microscopical and bacteriological examination, conducted by Dr. Ceresole, of vegetables commonly eaten in the raw state has yielded results which clearly demonstrate the importance of these as a possible source of parasitic and infectious diseases generally. The vegetables examined, consisting of lettuce, endives, radishes, fennel, and celery, were bought on the market and were first well washed with the excellent water of the Padua aqueduct so as to place them in the same condition as that in which they are usually eaten. They were then cut into small pieces with sterilised scissors, and placed in a sterilised flask of distilled and sterilised water. The water containing the particles detached from the vegetables after a vigorous shaking was then subjected to a direct microscopical and to a bacteriological examination. The former revealed an extraordinary quantity of animals belonging to various groups, rhizopoda, infusoria, worms, crustacea acarida, arachnida, and insects, some 52 species in all, mostly innocuous, but including amœba coli, balantidium coli, isotrica prostoma, and anguillula stercoralis. A great number of eggs of worms were found and among them some pathogenic species—namely, tænia echinococcus, oxyuris vermicularis, ascaris lumbricoides, trichocephalus dispar, and ankylostoma duodenale. By the bacteriological examination microbes were found in such myriads that a complete list of their species could not be made. For washing 100 grammes of vegetables 300 grammes of water were employed, and one cubic centimetre of the washings was found to contain on an average some 10,000 000 microbes, including bacillus coli communis, bacillus septicus, bacillus tetani, and a bacillus indistinguishable from bacillus typhosus. Of six animals inoculated with the washings heated for some minutes to from 70° to 80 C°, all died, five from malignant œdema and one from tetanus Of four animals inoculated with the washings not heated two died, one from malignant œdema and one from tetanus: the other two developed a large abscess at the seat of inoculation, from the contents of which pure cultures of streptococcus and staphylococcus pyogenes were obtained. The danger of eating salads made of vegetables containing this vast amount of parasitic and microbic life must be considerable. A thorough disinfection is, however, easily effected by soaking the vegetables for half an hour in a three per cent. solution of tartaric acid (about an ounce of acid to a quart of water).

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Syphilis in Asia Minor.

SYPHILIS has for a considerable time been increasing in certain provinces in Asia Minor, and has become so diffused that according to official reports 80 per cent. of the inhabitants are affected with it, and the Government has now ordered the adoption of measures intended to check the spread of the disease. Every year the Turkish Government selects for military service 12,000 men out of 20,000 in each *vilayet*, but in the *vilayets* where syphilis prevails the requisite 12,000 efficient recruits can only be obtained by selection from among 30,000 men, the remaining 18,000 being unfit for service. The provinces where syphilis has gained such a hold are Castamoni, Bartin, Erzingian, Angora, Ismidt (Nicomedia), and Adana, the last of which was added to the list only a few days ago. This prevalence of syphilis in these regions dates from the Russian occupation of Constantinople in 1830, when a force of 30,000 Russian soldiers was landed near Beicos on the Asiatic coast of the Bosphorus. It is the Moslem population who suffer most severely from the disease, for they consider an examination by a medical practitioner to be an offence against morality, especially if the patient happens to be a woman.

Death due to Corporal Punishment.

A pupil at a Turkish school in Scutari, one of the suburbs of Constantinople, died three days after the infliction of severe corporal punishment. During these three days he lay in a drowsy condition with occasional convulsive seizures, and at the necropsy it was found that the meninges were very much congested. The school teachers have been arrested. In Turkey corporal punishment in schools is forbidden.

The Accident to Professor Rieder.

Professor Rieder, who had the misfortune to fall from a building which was in course of construction, as mentioned in THE LANCET of Oct. 27th (p. 1245), is still confined to bed. Professor Schede, who was sent for from Bonn, did not discover any fracture of the spine; he connected a manometer with the spinal canal and found that the pressure of the cerebro-spinal fluid was higher than normal. The paralysis of the rectum and bladder still continues. The Sultan has conferred upon Professor Rieder the silver and gold medal of Imtiaz and has provided for him financially.

The Imperial Medical Society of Constantinople.

The meetings of the Imperial Medical Society, which take place every Friday, were resumed a month ago. The proceedings at the meetings include many valuable communications and discussions and the exhibition of interesting cases. The society was founded by the medical officers of the allied armies stationed in Constantinople during the Crimean war with the view of establishing a distinction between properly qualified medical men and irregular practitioners who had never attended a medical school. All the hygienic progress that has been made in Turkey during the last 40 years has been due to this society. The late Sultan Abdul Medjid, recognising the value of the society, took it under his patronage and granted it an allowance of £T50 per month, which has up to lately been paid regularly, but now the allowance is reduced to £C10 and is paid irregularly At the opening of the present session the President drew attention to the precarious financial condition of the society, which is so poor as to be unable to pay either the rent of the building where the meetings are held or the wages of the housekeeper, the only servant who is employed

The French Medical School at Beirut

Professor Morat and Professor Vallas of the Lyons Medical School have been directed by the French Government to proceed to Beirut in order to supervise and take part in the examinations which the students at the medical school there have to pass before obtaining their diplomas The Turkish Government has also sent two of the professors of the military medical school in Constantinople for the same purpose After having been approved by these French and Turkish professors the graduates of the Beirut Medical School are allowed to practise in Turkey without further examination, such as is obligatory on those whose qualifications have been obtained at other medical schools

Nov 10th

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

Medical Practitioners Act Amendment Bill

A BILL to amend the law relating to medical practitioners has passed through committee in the Legislative Assembly of New South Wales Many Bills with the same object have been previously rejected because the House thought that they went too far and gave too exclusive privileges to medical practitioners The present Bill is simply to enable the public to discriminate between the legally qualified and registered practitioner and the unqualified and unregistered quack It provides a heavy penalty for an unqualified person who assumes titles representing that he is a properly qualified medical practitioner or that he holds diplomas which he has not obtained Power is also given to the Medical Board to remove from the Register the name of any person who does not possess or has ceased to possess the qualification on which he has been allowed to practise, or has been convicted of certain offences, with a right of appeal to the Supreme Court

The Plague

The bubonic plague has practically ceased Seven weeks have elapsed since the last case occurred in New South Wales and no fresh cases have occurred in Victoria or South Australia The plague hospital at Sydney quarantine station has been disestablished, all the patients having been released, and Sydney is declared free from infection

Health of Sydney

The officer of health of the city of Sydney, Dr O E Corlette has issued a very comprehensive and interesting report on the sanitary condition of the city He states that extended powers are necessary in order to deal properly with a number of matters affecting the public health in the city, so that detailed provisions should be set out relating to such matters as the paving and draining of yards, the construction of stables, building over made ground definite rules as to foundations, damp proof courses, ventilation beneath floors, lighting and ventilation of rooms, and the prevention of overcrowding and of the storage of food materials in unsuitable places Dr Corlette points out that the vital statistics as at present obtained are fallacious, owing to ignorance as to the age and sex distribution of the population Concerning the housing of the poorer classes in Sydney Dr Corlette observes that a radical change is necessary Back to back houses exist, and the covering in of open areas at the rear of buildings has gone on to a serious extent He says that special provision must be made for housing the poorer classes in sanitary conditions by the erection of model dwellings at low rentals and the demolition of the buildings in which they were formerly housed; but that the condemnation of low grade dwellings by itself simply increases the pressure on the existing accommodation in the neighbourhood and causes increased overcrowding of dwellings, as in the case of Darling Harbour where houses were destroyed during the plague outbreak

Decline in the Birth rate in New South Wales

The vital statistics for the colony of New South Wales for the last year show that the birth rate continues steadily to decline The excess of births over deaths was 1 54 per cent representing a marginal loss of nearly one half during the past decade, the excess in 1888 being 2 36 per cent A notable feature is that the native born population reproduces nearly 20 per cent less than the immigrant portion of the community It is suggested that this state of affairs is due to the alarming prevalence of criminal abortion and the unrestrained advertising of those who practise it in the public press Lately legislation has been passed to suppress such advertisements and it will be interesting to see if any improvement in the birth rate will occur in the next few years

The Australian Natives Association and the Medical Profession of New South Wales

Reference was made in a previous communication to the establishment in New South Wales of the Australian Natives' Association as a friendly society At a meeting of the Council of the New South Wales Branch of the British Medical Association, held on August 7th, it was resolved •

> That the Australian Natives Association as at present constituted is prejudicial to the interests of the medical profession in terms of Article of Association 35a and that a circular embodying the foregoing resolution be sent to all members of the medical profession

On August 31st a general meeting of the medical profession was held to consider the matter, Dr P Sydney Jones being in the chair, and there was a large and representative gathering Dr Sydney Jamieson moved—

> That this general meeting of the medical profession endorses the resolution of Jan 10th 1896—viz, that medical aid and benefit societies are intended for the poorer members of the community and not for the well to-do, and that in the opinion of this meeting it is not desirable that people in receipt of incomes of over £200 per annum should receive medical attendance and medicine from societies as at present organised

Dr Jamieson pointed out that the Australian Natives' Association adopted no wage limit, that the members, on the contrary, enrolled a better class than the ordinary friendly society, and that in Victoria such people as well paid civil servants, bank managers, parliamentary and municipal magnates, land owners, and business men were found as benefit members The rate of pay for their medical officers was fixed at less than 15s per annum; and no extra fees were allowed except for midwifery The motion was seconded by Dr Abbott, and after some verbal amendment was carried The second motion was brought forward by Dr W H Goode —

> That this meeting approves of the course adopted by the council of the New South Wales Branch of the British Medical Association in calling attention to the action of the Australian Natives Association and declaring it a society 'prejudicial to the interests of the medical profession

Dr R S Bowker seconded this motion, which was carried Dr R Worrall in a very earnest speech moved that—

> This meeting earnestly appeals to those members of the profession whose advice is sought in consultation to refrain from meeting medical officers to associations which have been declared ' prejudicial to the interests of the medical profession

Dr Angel Money seconded this motion, which also was carried Finally, it was resolved to suggest to the New South Wales Branch of the British Medical Association that it should form a permanent investigation committee to collect and circulate information which may be of use to the profession in their dealings with friendly, benefit, and medical aid societies, and hospitals and kindred institutions, and any other matters affecting the welfare of the medical profession throughout Australasia

Queen Victoria Home for Consumptives

At the time of the Jubilee funds were subscribed to establish homes for consumptives in commemoration of the Queen's Jubilee, but so far nothing has been done The third annual meeting of subscribers to the fund was held on Sept 26th The report stated that the only thing done had been to maintain the Thirlmere Home where 94 patients had been admitted, of whom 26 were benefited, 24 had died, and 44 were unrelieved The average cost per bed per annum was £34 16s 2d The large number of deaths and unrelieved cases was due to indiscriminate admissions of necessitous and urgent cases in the last stages of the disease The committee had decided in future only to admit such cases as could reasonably be expected to be so far restored to health as to be able to resume work of some kind The committee had waited on the Colonial Secretary to urge the Government to establish a hospital for poor persons in advanced stages of the disease

A Medical Libel Action

Mr J W O Brien, F R C S Irel, brought an action in the Supreme Court, Melbourne, against Mr Thomas Scott, M.R.C.S., for the recovery of £1000 damages for alleged libel, which consisted of two paragraphs written by defendant which appeared in the *Warrnambool Standard*, stating that the plaintiff, as honorary surgeon to the local racing club, had improperly treated an injured jockey. The case was settled out of court, Mr. Scott stating that he had discovered that there was no ground for his remarks about Mr. O'Brien and agreeing to pay £400 costs.

Conflicting Medical Evidence.

At an inquest on the death of a patient in the Albury Hospital some conflicting evidence was given by the medical men concerned. Dr. Schlink had certified that the man was insane, but Mr. Andrews, the Government medical officer, said that he was not insane, but that he was a fit patient for the hospital when he died. Mr. M. O'Shaughnessy deposed that death was due to obstruction of the bowel. Mr. Andrews, Dr. Muller, and Dr. Schlink said that the cause of death was lead poisoning. The coroner found, in accordance with the preponderance of the medical evidence, that deceased died from lead poisoning.

An Explanation.

In a letter in THE LANCET of August 25th (p. 631) Mr. W. B. Vance insinuated that the account given by your Australian correspondent of what he calls "the O'Hara case" was incorrect and biased. In writing it I took special pains to give an impartial statement of facts, which could nearly all be corroborated by documentary evidence. Having critically re-read it I affirm that every statement made in my letter in THE LANCET of May 26th (p. 1554) is correct, with one exception—viz., in the account of the meeting (of which at the time of writing there was no authenticated report other than that which had appeared in the newspapers) it is stated "the others" referring to Dr. Macansh and Mr. Cuscaden, "admitted Mr. O'Hara's culpability." It should have been, instead of "others," Mr. Cuscaden, as I find on referring to the report in the *Australasian Medical Gazette*, where he only is reported to have said, "I also agree with the Council that a breach of ethics has been committed." I regret this unintentional mistake, the result largely of condensation. A comparison of the authenticated report of all the proceedings given in the *Australasian Medical Gazette* of April 25th will show that my account was otherwise correct.

Oct. 10th.

Medical News.

UNIVERSITY OF BRUSSELS.—The following practitioners have satisfied the examiners and obtained the M.D. degree:—

H. M. W. Bridgman, Alassio, Italy, and London; A. V. Johnson, Kensington; E. Winckler King, Bombay; W. M. Permien, Allahabad; John R. O'Brien, Great Yarmouth; and A. J. Treasuryvala, Bombay.

Nine candidates entered.

ROYAL COLLEGE OF SURGEONS IN IRELAND: DENTAL EXAMINATION.—Mr. John Isidore Potter having passed the necessary examination has been admitted a Licentiate in Dental Surgery of the College. The following candidates have passed the primary part of the examination: Mr. T. Beaumont, Mr. G. Friel, and Mr. L. Goldfoot.

NEWTON ABBOT WORKHOUSE.—Mr. J. W. Ley, F.R.C.S. Eng., has collected over £40 and purchased two pianos for the use of the inmates of Newton Abbot (Devon) Workhouse.

TYPHOID FEVER AT PLYMOUTH.—An outbreak of typhoid fever has occurred at Plymouth and the medical officer of health (Mr. F. M. Williams) has traced the cause to contaminated milk supplied from a small dairy-farm outside the borough boundary at Egg Buckland. The typhoid fever ward of the Borough Infectious Diseases Hospital was only built for the accommodation of 16 patients, although on Nov. 15th it had 23 cases. The sanitary committee will open the scarlet fever block, which is empty, and also will fit up the old laundry with beds. The committee will recommend the Town Council at once to complete the enlargement of the isolation hospital. 55 cases of typhoid fever have been notified in Plymouth up to Nov. 20th.

ERRATUM.—ENTRIES AT THE MEDICAL SCHOOLS.—The figures for University College, Sheffield, given in THE LANCET of Nov. 3rd (p. 1283), should read as follows: Full medical course 1900-1901, eight; special classes, two; dental, one; full medical course 1899-1900, five; increase, three.

A MEDICAL GOLF TOURNAMENT, which was recently concluded at Trafford-park, proved a great success. There were about 60 entries. Mr. W. J. Baird of Springwells, Bury, who was fortunate in having two walk-overs, played a consistently steady game throughout with a handicap of 7 and won the tournament, beating Mr. P. Worley of Pendleton, handicap 9, by 3 up and 2 to play.

ROYAL GEOLOGICAL SOCIETY OF CORNWALL.—At the annual meeting of this society held at Penzance on Nov. 13th the President (Mr. J. D. Enys) presented Dr. Clement Le Neve Foster, inspector of metalliferous mines for North Wales, with the William Bolitho Gold Medal in recognition of the distinction which he has attained as a mineralogist and also of the great services rendered by him to the society as curator during the period when he held the appointment of inspector of mines for Cornwall and Devon.

MUNICIPAL HONOURS AND MEDICAL MEN.—In addition to those whose names were published in THE LANCET of Nov. 17th (p. 1451) the following members of the medical profession have been elected or re-elected mayors:—Bolton: Mr. J. E. Scowcroft, M.D. St. And. (re-elected). Carnarvon: Mr. W. J. Williams, L.R.C.P. Edin., L.F.P.S. Glasg. (re-elected). Cheltenham: Mr. G. Norman, M.B., B.S. Durh. (re-elected). Crewe: Mr. Charles Wilson, M.D. Glasg. Pwllheli: Mr. S. W. Griffith, L.R.C.P. Edin., L.R.C.S. Edin. (re elected). Saffron Walden: Mr. John Parkinson Atkinson, M.D. Glasg.

CENSURE OF A PUBLIC VACCINATOR.—At the meeting of the Bideford (Devon) Board of Guardians held on Nov. 13th a communication was read from the Local Government Board in reference to one of the public vaccinators of the union. The letter stated that out of 405 vaccinations by the officer referred to only 95 were performed by him, the remainder having been done by his deputy. The Local Government Board considered this improper, as only when it was absolutely necessary should the deputy perform the operation; they thought that the contract ought to be determined, but they desired to have a written explanation from the public vaccinator in question.

THE members of the London Hospital Medical Club held their annual dinner on Nov. 15th, when Mr. E. H. Openshaw was the guest of the club on his return from South Africa. A good muster of the members supported the chairman, Mr. C. W. Mansell Moullin, in giving a hearty welcome to their guest. In response to the toast of his health Mr. Openshaw gave an interesting account of his experiences, not the least exciting being a graphic description of the running down of the ill fated *Mexican* by the boat on which he was a passenger. Mr. Openshaw also exhibited a large number of photographs illustrating the various phases of the country through which he travelled.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

AUBREY, THOMAS, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Newmarket Union, vice A. G. L. Campbell, resigned.

BONNER, T. J., M.B., C.M. Aberd., has been appointed Medical Officer by the Towyn District Council, vice B. M. Bone, resigned.

BRADY, CHARLES M., L.R.C.S. Irel., L.A.H., has been appointed Honorary Medical Officer to the Royal Albert Edward Infirmary, Wigan, vice R. Hamilton Cowan, deceased.

BROWNE, ADA M., L.S.A., has been appointed Assistant Anæsthetist to the Chelsea Hospital for Women.

CREAN, JOHN JOSEPH, Lieutenant-Colonel, L.R.C.P. & S. Irel. (retired list Royal Army Medical Corps) has been selected for duty with the troops at Brighton.

EDWARDS, C. W., F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Wincanton District of Somersetshire.

Fenn, C. F., M.B. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon, Worcester Infirmary.

Field, R. O., M.B. Lond., has been appointed *pro tem.* Medical Officer of the Patrington Union, vice E. Robinson, resigned.

Fuller, A. W., M.B., Ch.B. Edin., has been appointed Assistant House Surgeon to the Rotherham Hospital and Dispensary.

Fullerton, Andrew, M.D., has been appointed Surgical Registrar to the Royal Victoria Hospital, Belfast.

Fulton, Wm., M.B., C.M. Glasg., has been re-appointed Parochial Medical Officer by the Stevenston Parish Council.

Hayden, W. Falconer, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the County Hospital, Newport, Monmouthshire.

Iles, Mary M., M.B., B.S. Lond., has been appointed House Surgeon to the General and Children's Hospital, Walthamstow, N.E.

Jones, Herbert, L.R.C.S. Irel., D.P.H. Cantab., has been appointed Medical Officer for the Combined Sanitary Districts for rural Herefordshire, vice H. V. Sandford, resigned.

Kenwood, H. R., M.B., C.M. Edin., L.R.C.P. Lond., D.P.H., has been appointed Medical Officer for the Borough of Stoke Newington.

McGilmont, John, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Parochial Medical Officer by the Stevenston Parish Council.

Nicholas, James Hamilton, Major, L.R.C.P. Irel., L.R.C.S. Edin., (retired list Royal Army Medical Corps) has been selected for duty with the Southern District at Gosport.

Oyston, W. P., M.B., Ch.B. Vict., has been appointed Certifying Surgeon under the Factory Acts, for Osmotherly District.

Shaw-Mackenzie, John A., M.D. Lond., has been appointed Physician to Out-Patients at the Samaritan Free Hospital for Women and Children, Marylebone-road, London, N.W.

Stanford, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer, Hollingbourn Union, vice E. S. Webber, resigned.

Starkey, William, M.B., B.Ch. Irel., has been appointed Assistant Medical Officer to the Down District Asylum.

Steed, John, M.D. Edin., has been appointed Medical Officer to Jarvis's Charity, Staunton-on-Wye, vice W. E. Barton, resigned.

Tyrnau, F. J. W., L.R.C.P., L.R.C.S. Irel., has been appointed District Medical Officer, Smallburgh Union, vice A. Crisp, deceased.

Trevor, R. Salusbury, M.A., M.B., B.C. Cantab., has been appointed Assistant Curator of the Museum, St. George's Hospital, Hyde Park Corner, London.

Walker, E. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of the Luddenden Sanitary District, Halifax Union, vice E. E. Crowther.

Ward, J. A., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Training Ship *Shaftesbury*, Grays, vice W. Robertson, resigned.

Wearne, Walter, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for the Borough of Helston (Cornwall).

Wild, G. S., M.D. Durh., M.R.C.S., has been appointed Honorary Physician to the Bootle Borough Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham and Midland Eye Hospital, Church street, Birmingham.—Assistant House Surgeon. Salary £60 per annum, with apartments and board.

Brentford Union.—Assistant Medical Officer for the new Infirmary, unmarried. Salary £100 per annum, with furnished apartments, rations, washing, &c. Subject to statutory deductions. Apply to the Clerk to the Guardians, Union Offices, Isleworth, W.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £80, with board and lodging in the Infirmary.

Brighton and Hove Lying-in Institution and Hospital for Women, 76, West-street, Brighton.—House Surgeon, unmarried. Salary £80 per annum, with furnished apartments, board, gas, coals, and attendance.

Brixton Dispensary, Water lane, Brixton.—Resident Medical Officer for two years, unmarried. Salary £150, with furnished apartments, attendance, coal, and gas.

Bury Infirmary.—Junior House Surgeon. Salary £80, with board, residence, and attendance. Apply to Hon. Secretary, Dispensary, Knowsley road, Bury.

Cardiff Infirmary.—Assistant House Surgeon for six months. Salary at the rate of £75 per annum, with board, washing and apartments.

Central London Sick Asylums District.—Second Assistant Medical Officer and Dispenser at the Asylum at Hendon for twelve months. Salary £75 per annum, with board and residence. Subject to statutory deduction. Apply to the Clerk, Cleveland street Asylum, Cleveland street, W.

Children's Hospital, Forest House, Nottingham.—House Surgeon for six months, unmarried. Females ineligible. Salary at the rate of £100 per annum, with board and residence.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Second House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

Clayton Hospital and Wakefield General Dispensary, Wakefield.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, lodging and washing.

Clinical Research Association, 1, Southwark street, London.—Assistant Pathologist. Commencing salary £125 per annum.

Croydon General Hospital.—House Surgeon for one year, unmarried. Salary £105, with board, lodging and washing at the hospital.

Darlington Hospital and Infirmary.—House Surgeon, unmarried. Salary £150 per annum, with rooms in the Institution. Applicant to board himself.

East London Hospital for Children and Dispensary for Women, Glamis-road, Shadwell, E.—House Physician. Board, residence, &c., provided and an honorarium of £25 given conditionally.

Government of Ceylon.—Medical Man for the Ceylon Medical College, for the post of Registrar, Curator of Museum, and Lecturer. Salary Rs. 6000 per annum, rising by triennial increments of Rs. 500 to Rs. 8000.—Address, Private Secretary, Colonial Office, S.W.

Guest Hospital, Dudley.—Assistant House Surgeon, for six months. Salary at the rate of £40 per annum, residence, board, and washing.

Hospital for Sick Children, Great Ormond street, London.—Resident Medical Superintendent for one year. Salary 100 guineas, with board and residence in the Hospital.

Huddersfield Infirmary.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

Hull Royal Infirmary.—Honorary Surgeon. Also Assistant House Surgeon for one year. Salary £60, with board and furnished apartments.

Leeds Public Dispensary.—Junior Resident Medical Officer for one year. Salary £100, with board and lodging.

Leicester Infirmary.—Assistant House Surgeon for 12 months. Salary £80, with board, apartments, and washing.

London Hospital Medical College, Mile-end, E.—Assistant Demonstrator of Anatomy. Salary £30 a year.

Manchester Children's Hospital, Gartside street, Manchester.—Assistant Surgeon. An honorarium of £50 per annum will be given.

Miller Hospital and Royal Kent Dispensary, Greenwich road, S.E.—Junior Resident Medical Officer for six months. Salary at the rate of £60 per annum, with board, attendance and washing.

Ramsgate and St. Lawrence Royal Dispensary and the General Hospital and Seamen's Infirmary.—Resident Medical Officer, unmarried. Salary £100 per annum, with furnished apartments, board, and attendance.

Royal Albert Hospital, Devonport.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board, lodging, and washing.

Royal Hospital for Children and Women, Waterloo bridge-road, London.—Resident Medical Officer for twelve months. Salary £70, with board and laundry. Also Assistant Physician.

Royal Hospital for Incurables, Donnybrook, Dublin.—Resident Medical Officer for one year. Salary £100, with board and furnished apartments.

Seamen's Hospital Society ("Dreadnought"), Greenwich, S.E.—House Physician for "Dreadnought" Hospital. Salary £75 per annum, with board and residence.

St. Mary's Hospital for Sick Children, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary £80 per annum, with board, residence, laundry, &c.

St. Mary's Hospital Medical School, Paddington.—Lectureship in Chemistry and Physics. Salary £150 per annum, with extra fees for London University Classes.

Throat Hospital, Golden square, London.—Non-resident Junior House Surgeon. Salary £100 per annum, with luncheon daily.

Trinidad Government Lunatic Asylum.—Assistant Medical Superintendent. Salary £250 and £50 allowance, rising by quinquennial increments of £50. Furnished quarters for unmarried man in the Asylum. Free passage provided. Appointment pensionable. Applications to the Private Secretary, the Colonial Office, S.W.

University College, London.—Assistant Surgeon.

University of Glasgow.—Two additional Examiners for degrees in Medicine. Annual salary £30 in each case.

West London Hospital, Hammersmith road, W.—House Physician and House Surgeon, for six months. Board and lodging provided.

Births, Marriages, and Deaths.

BIRTHS.

Barlow.—On Nov. 16th, at Dalston lane, N.E., the wife of Thos. Carey Barlow, L.R.C.P. Edin., of a son.

Beadles.—On Nov. 17th, at Battle Cottage, Sydenham, S.E., the wife of Arthur Harry Beadles, M.R.C.S., L.R.C.P. Lond., of a son.

Bundey.—On Nov. 16th, at Honor Oak park, the wife of H. Marchant Bundey, M.B., C.M. Edin., of a daughter.

Hudson.—On Nov. 16th, at Vine House, Cobham, Surrey, the wife of Arthur B. Hudson, M.R.C.S., L.R.C.P. Lond., of a daughter.

Pitt.—On Nov. 19th, at Portland place, W., the wife of G. Newton Pitt, M.D. Camb., of a son.

Scott.—On Nov. 15th, at Shooters hill road, Blackheath, the wife of Patrick Cumin Scott, M.B. Cantab., of a son.

MARRIAGES.

Anderson—Turnell.—On Nov. 5th, at St. Augustine's Church, Sheffield, Alexander Anderson, M.B., D.P.H., Wadsley lane, Sheffield, to Florence Ida, second daughter of the late Samuel Turnell, Sheffield.

O'Keeffe Wilson—Light.—On Nov. 14th, at Christ Church, Sefton park, Liverpool, George O'Keeffe Wilson, L.R.C.P.I., L.R.C.S. Irel., of Dublin, to Florence Gwendolen, eldest daughter of James Barclay Light, Liverpool.

DEATHS.

Beardsley.—On Nov. 20th, at The Towers, Grange-over-Sands, Amos Beardsley, M.R.C.S. Eng., aged 73 years.

Cockle.—On Nov. 15th, at The Lodge, West Molesey, John Cockle, M.D.

Mackay.—On Nov. 20th, suddenly, at Learmonth terrace, Edinburgh, George Mackay, M.D., *Deputy Surgeon-General, Madras Army*, retired, in his 81st year.

Higgall.—On Nov. 15th, at Elgin-crescent, W., Edward Higgall, M.R.C.S., aged 82.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL EVIDENCE AT CORONERS' INQUESTS.

We have in these columns constantly called attention to the fact that the absence of medical evidence at coroners' inquests may endanger the course of justice. The want of a proper medical explanation of the cause of death may enable a criminal to escape justice or may leave some catastrophe unexplained to the detriment of the reputation of persons who have been in association with the deceased. Two examples have recently come before us where inquests have been conducted without medical evidence although medical evidence was clearly required and was for that matter tendered in a fashion by persons not in a position to give it properly.

The first case occurred at Aberford, near Leeds, and was an extraordinary case because the subject of the inquest, who had committed suicide, was only eight years old. He was at a private boarding school and had been admonished on the way home from church for an exhibition of temper. He was sent to his bedroom with his Bible to learn some verses and was shortly afterwards discovered hanging by a rope from the bedstead. Mr. J. H. Wigham, acting for Mr. T. B. Abbott of Aberford, was called in and pronounced life extinct. At the inquest, which was held at the school, it was elicited that the boy was weak in health and of a reserved disposition, being inclined to sulk when rebuked and preferring to play alone. His schoolmaster gave evidence as to the position in which he found the body hanging and the first-aid assistance which he administered. A woman who laid out the body deposed that there were no marks on the deceased with the exception of a blue one round his neck. The coroner in summing up pointed out that the schoolmaster's conduct was wise and exemplary. There was no evidence of bullying on the part of the unfortunate child's schoolfellows and the jury returned a verdict of "Suicide during a paroxysm of rage."

In the second case an inquiry was held upon a cabdriver who died from the effect of injuries received while driving a party in a landau from Dorchester to Portland. At the inquest it was elicited that during this drive the party had stopped at a public-house near Dorchester and at another, the Crown Hotel in Weymouth, where "they had a few drinks" according to the evidence of one of the party and where they stayed "a considerable time, perhaps three-quarters of an hour," according to an eye-witness. A short time after leaving the hotel at Weymouth the driver, a man named Spencer, fell over the side of the landau under the wheels, two of which passed over his chest. Four minutes later Mr. D. T. Key, of Wyke Regis, near Weymouth, arrived and saw at once that he had a bad case to deal with. The employer of the unfortunate man wanted to take charge of him, but this Mr. Key would not allow as he did not think the employer sober, and the crowd, who seemed to hold the same view, led the employer away. After a time some policemen arrived and Spencer was lifted into the landau and Mr. Key accompanied him to the Weymouth Hospital. But while he lay on the ground one of the men who had been in the carriage came back and kicked him, saying, "Get up, you lazy ——." Four or five days afterwards Spencer died in Weymouth Hospital, and at the necropsy he was found to have five broken ribs as well as injury to the lungs. Mr. Key was not called by the coroner to give evidence. The jury brought in a verdict of "Accidental death," the foreman adding that Spencer was not in a fit condition to drive.

In the first of the cases which we have related no public harm is done by the fact that proper medical evidence was not invited. No suspicion of injudicious treatment rests upon the schoolmaster or of bullying upon the victim's schoolfellows. But these things might very well have been otherwise. We have only the word of the woman called in to lay out the body in support of the fact that the deceased had no other injuries than a blue line round his neck. Clearly the medical man who was called to the case at once ought to have been asked to state the medical opinion that death occurred by hanging and to have given the medical testimony that the deceased had no other lesions. If such evidence was required at all it should have been given by the only person who was qualified to give it. In the second case the absence of medical evidence is more obviously wrong. The circumstances under which Spencer fell from his box do not appear to have been made clear, though we agree with the foreman of the jury that he was probably too drunk to be capable of driving. The tragedy occurred during election time. The landau appears to have contained a group of semi-drunken men who stopped at various public-houses and regaled themselves with champagne and beer and who sang songs and skylarked. One of the parties received injuries leading to his death, and from that time forward the most important witness who could possibly be called was the medical man who appeared on the spot four minutes after the accident. He could have given the best evidence as to the condition of Spencer, as to the inebriety of the party, and as to the brutality of the person who kicked the injured man on the ground. From the time of his arrival on the scene Mr. Key took charge of the patient, saved him from his friends, and delivered him to the hospital. He alone could have made the story of the death of Spencer a clear one, while it is possible that his evidence might have led to the arrest and salutary punishment of a lot of drunken, brutal Hooligans. This is only a supposition, but there would be no just basis for such suppositions if proper medical evidence had been forthcoming at the inquest.

"HAVE MATERNAL IMPRESSIONS ANY EFFECT ON THE FŒTUS IN UTERO?"

To the Editors of The Lancet.

Sirs,—Having read Dr. William Duncan's paper on the above subject in The Lancet of Nov. 3rd (p. 1266), it has occurred to me that the following case which has come within my own experience may not be without some interest, and for this reason I beg leave to publish it in your columns, although it is only one of many similar cases which have from time to time been recorded. A boy, about nine years old, while playing with some friends at a large children's party ran headlong into a fence of barbed wire, with the result that his left cheek was torn open from the angle of the jaw to within an inch of the mouth, leaving a nasty gaping wound. A lady who was some months advanced in pregnancy was present and saw the child shortly after the accident, and was greatly horrified at his appearance. In due course she gave birth to a girl, and on the infant's left cheek was a nævus corresponding exactly in position and direction to the wound she had seen on the little boy's face. The girl is now grown up and still retains the birthmark on her cheek, though it has faded somewhat with the lapse of time. I am, Sirs, yours faithfully,

Thomas J. T. McHattie, M.B., Ch.B. Edin.

Holloway-road, N., Nov. 7th, 1900.

To the Editors of The Lancet.

Sirs,—Having read the article under the above heading by Dr. Duncan in The Lancet of Nov. 3rd (p. 1266), I think that the following cases may be interesting to those medical men who look upon such cases as more than mere coincidences. On March 28th, 1893, Mrs. X—— brought a little boy to me suffering from a simple fracture of the lower end of the left humerus, which had been caused by being run over by a bicycle. On Sept. 5th, 1893, Mrs. X—— was delivered of a fine male child with a so-called intra-uterine amputation of the left forearm an inch below the elbow and with rudimentary fingers. In August, 1890, I attended Mrs. Y——, a multipara whose preceding labours had been normal. On my entering the room she said that she was certain something was wrong because she had visited Barnum's show in London when a few weeks pregnant and she felt sure that seeing the "freaks" had affected the child. In about three hours I delivered her of an anencephalous monstrosity. How maternal impressions act I do not pretend to know, although it seems comprehensible that in the case of nævi a "nervous impression" might in some way disturb the arrangement of the blastodermic cells.

I am, Sirs, yours faithfully,

Grimsby, Nov. 12th, 1900. T. W J. Allen, M.D. Durh.

AN AMERICAN ADVERTISEMENT.

In a popular lecture given by a medical man some time ago he drew attention to an advertisement which at one time appeared on the inner cover of yellow-back railway novels, describing the advertiser's pills as "not fooling round like other pills" but doing their work at once. From an American medical magazine we print the following, which would make a good companion advertisement to that of the volatile pills:—

> "As a chaser after a Welsh Rabbit, I want nothing better than ——— Tablets," says a prominent physician. They're good lobster chasers too—Try them yourself, Doctor.

Such advertisements in medical journals may be funny but they are not dignified.

"HOSPITAL ABUSE: A SIDE THAT IS SOMETIMES OVERLOOKED."

To the Editors of The Lancet.

Sirs,—I have read with interest the letters of your correspondents on this subject in The Lancet of Nov. 3rd (p. 1320) and 10th (p. 1396), and as a general practitioner of over 20 years' experience in several parts of London I am convinced that there is a great deal of truth on both sides of the question as enunciated by the letter of "Hospital Surgeon" and "A General Practitioner." The great and practical fact, however, remains that abuse of hospitals continues, both by members of the hospital staff in encouraging all sorts and conditions of patients to the injury of the general practitioner and by the general practitioner in sending to hospitals cases which he is either unwilling to take up himself or patients who could well afford to pay a consultant's fee. It is at present my lot to be in practice in the neighbourhood of the Docks, my practice almost entirely being not among the dock employés but with the skilled mechanics and labourers who are employed in the many large factories in this district. The practice in this neighbourhood was until a few years ago good for a working-class district and there was plenty of surgical work (in consequence of the numerous accidents in the factories), which was well paid for by the employers. Then a change came o'er the scene; a branch of the "Seaman's *Dreadnought* Hospital Society" was established at the Albert Dock, and will it be believed that although this was a hospital for seamen, women and children were at once encouraged to attend the out-patient department from all the surrounding districts. No inquiries are made and no connexion with the sea is necessary. It is the common habit now for the men, women, and children of the mechanics here to flock to this hospital for every trivial complaint and the large firms send every accident that occurs there at once, and so the private practice of the district has been ruined by the unfair competition of this charity and, as *I maintain, by the misapplication of* the funds which, I presume, are subscribed for "seamen." The reason of this is not far to seek—viz., this, the large firms in the neighbourhood finding that it pays them better to subscribe to the hospital and send all their accidents there rather than to pay a private practitioner, the hospital as a *quid pro quo* throws *open its doors* to *their employés as out-patients.* When I say that among the mechanics here I am able on occasions to obtain fees of five, *four*, never less than three, guineas for the services of a consultant, it is evident that an indiscriminate and pauperising charity such as this is out of place in a district where even labourers can and do pay as much as from 8s. to 12s. a week rent. Personally I always make a point of feeing a consultant rather than sending the case for hospital advice when I consider a second opinion advisable, neither do I ever send cases to hospital which can be *treated* at home within *the means of the patient and* the capacity of the medical attendant; but in the face of the treatment meted out to us by the hospitals I ask what encouragement is there for general practitioners to do this? It is the *reckless system of* hospital abuse which is making the general practitioner regard the hospital physician and surgeon as his enemies and naturally, therefore, he not only becomes indifferent as to their welfare, but anxious to shift on to their shoulders the burden of those cases which are unremunerative or uninteresting to himself; and this state of things will continue until he can be brought to see that the consultant regards him as a man and a brother who has also "a right *to live" and not to be regarded, as he so often is, as an ignorant person* from whom every patient who applies for hospital relief has had a lucky escape.

A great deal has been made of the fact that in some of the large hospitals a special officer has been appointed for the purpose of making inquiries into the circumstances of the out-patients. I had occasion a short time since to make a personal investigation into this system at one of the largest London hospitals, and I found that although there certainly was such an officer the system of his inquiry amounted to this—that every applicant for relief was valued by him as being able to afford a certain sum from 1d. to 2s., and was asked to contribute that to the hospital funds before being sent into the consulting room. At a certain "special hospital" I know it to be even worse, for there every decently dressed person is requested to go to the private house of the consultant and to pay a reduced fee, and at this same hospital I know of a woman who has attended regularly for months once a week who pays the porter 2s. 6d. each time to be sent in early. These are by no means *isolated cases. Many such, no doubt,* come within *the daily* experience of every general practitioner and, I need scarcely add, do *not tend to foster that esprit de corps* without which there can be no remedy for the present lamentable state of affairs within the profession and through which we have become the prey not only of the public but even more of those who pull the strings of hospital charity.

I am, Sirs, your faithfully,

Nov. 12th, 1900. GENERAL PRACTITIONER.

THE CASE OF MR. JOSEPH HENDERSON MARTIN.

To the Editors of THE LANCET.

SIRS,—In addition to the £5 4s. 6d., the receipt of which was acknowledged in THE LANCET of Nov. 17th, the following subscriptions have been since received by Dr. W. M. Renton and myself.

I am, Sirs, yours faithfully,

H. LYON SMITH

The Hawthorns, Chester-le-Street, Nov. 21st, 1900.

"MOTOR CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Motor-car," in THE LANCET of Nov. 3rd (p. 1320), does he seriously mean that eight out of 10 motor-cars are in "hospital"? To begin with the statement is absurd, and the point is *this—probably nine out* of 10 so-called "breakdowns" of motors are due to the ignorance or carelessness of drivers. "Motor-car" says I have been very lucky; that may be, but I know other automobilists who have the same class of car, that is, Benz or International, who have had less trouble than I have had, because they either have an engineer or are better mechanics than I am; and conversely, the man who has no mechanical skill has much more trouble. In my practice *three or four horses were* always *necessary* and "Motor-car" knows, possibly, the trouble it used to be *for evening or night visits to hunt up* one's coachman and wait about while he harnessed his horse, growling the while at having "cleaned his harness," and so on. Has "Motor-car" never waited half an hour for his horse to be roughed? I have had quite enough of horses to last me the rest of my life. Shying, bolting, laminitis, influenza, nail driven wrong, are only a few of horse worries, let alone the "beggar goes and dies." I have driven about 12,000 miles in my car in two years, in all weathers over atrocious roads, at an inclusive *cost of less than 2d.* a mile. Can this be done with a horse and at the speed of a motor-car? Take one instance. I have had a morning and evening visit six miles from home, besides my other work, that is 24 miles. I took two hours to do it; with a horse and dog-cart it would take me three hours, thus, on two visits, a whole working hour is saved. Roughly this saving goes on every day. To my mind the comfort, saving, and convenience of a motor-car are beyond calculation. *As to my worries with chains, tyres, and wheels, they have* not troubled me at all since the first six months, when I had the first lot off. I confess nearly all my "roadside repairs" have been due to careless*ness or want of experience in driving.* "*Motor-car" thinks £30* a year a "large order" for doing 6000 miles a year. How much would it cost him from first to last doing it with horses? I know very well!

I am, Sirs, yours faithfully,

Nov. 12th, 1900. BENZ CAR.

"NOTES ON AN OLD ENGLISH HOUSE."

WE have received under the above title a copy of an interesting sketch of the history of the old business of Messrs. Burgoyne, Burbidges, and Co., the well-known firm of wholesale and export druggists and manufacturers, of 12 and 16, Coleman-street, E.C. The business was founded as far back as 1741, and has therefore been in existence for over one and a half centuries The sketch contains numerous illustra*tions of the laboratories* and *works* and *facsimiles are published of* formulæ from the firm's oldest laboratory book, the date being 1742.

THE MEDICAL PROVIDENT LEAGUE.

WE have received many letters about this body. Space does not permit us to discuss the scheme at length this week. We recommend those who have written to us, and others, not to join the League, and will give *our reasons in our next issue.*

WHOLESALE DRUG HOUSES AND THE PUBLIC.

To the Editors of THE LANCET.

SIRS,—*No* doubt the profession as a whole will join with me in a growl, for oftentimes we can only hope to obtain what we require by indulging (*of* course in a nice way) in the process. The present grievance is against the wholesale drug houses in supplying retail to the public palatinoids, jelloids, and other up-to-date preparations. My chemist here tells me that ladies (especially) come constantly to him for such and such a preparation (*giving name of house, number of* drug, and retail price, &c.). Such a proceeding I do not consider at all correct and I feel sure no medical man will countenance it. The only remedy for us to adopt will be either to write prescriptions in Greek, German, or Arabic or not to prescribe in writing at all and to cease to get such drugs from the wholesale houses. Can any member of the profession make a better suggestion? I never use such expressions as "jelloids," "palatinoids," or any other 'oids to my patients; why should others cut their own throats by so doing? Besides, the system is dangerous from the public side of the question; one can get such a thing as an overdose, or "push" a drug too far. The present system of advertising new remedies in chemists' shops tends to reduce what is a purely scientific profession to the level of quackery.

I am, Sirs, yours faithfully,

Horsham, Nov. 6th, 1900 GEO. SELKIRK JONES.

"A WELL-KNOWN BONE-SETTER."

THE following paragraph is taken from the *North-Eastern Gazette.* It appeared on Nov. 15th and again in another local paper on *Nov. 16th*:—

> "We are glad to hear that Mr. Pike Pease, M.P., is making satisfactory progress. His injured knee has been successfully treated by Mr. Clayton, the well-known bone setter."

It is astonishing, as Mr Crummles said, how these things get into the papers.

THE INTERMEDIATE EXAMINATION IN SCIENCE AT LONDON UNIVERSITY.

To the Editors of THE LANCET.

SIRS,—I shall feel greatly obliged *if some of your readers can advise* me through your columns as to the text books to read *for* the Intermediate Examination in Science at the University of London

I am, Sirs, yours faithfully,

S. B. C.

"THE EXTRACTION OF TEETH FOR CLUB PATIENTS."

To the Editors of THE LANCET.

SIRS,—In reply to the letter under the above heading signed "Junior" in THE LANCET of Nov. 10th, p. 1395, I should like to tell your correspondent that it is not customary for medical officers of clubs to extract teeth gratuitously for members I should advise him to continue to charge the usual 1s for tooth extraction. Further, I should advise him not to be tempted to imitate the complaisance of his neighbouring medical brethren but to limit rather than to extend his contract work. I have always limited my club work by the literal meaning of the words "medical attendance and medicine" in the rules of clubs—that is to say, I give no pills, ointments, or liniments. When I commenced club work I scheduled certain things which would require extra fees, such as fractures, dislocations, operations, burns and scalds, venereal diseases, &c. Twelve months afterwards a member refused to pay for attention to fractured fingers and as a matter of principle was involved I fought the case through three successive hearings at the county court, unaided by any defence union, and won a verdict. *En passant*, the judge supported an old contention of mine, that in unison with the duties I was appointed under the rules to fulfil, my proper title was not the antiquated one of "Surgeon," but "Medical Officer." The British workman is only too pleased to get as much as he can for his money and although he objects to be sweated himself he enjoys the process on other people. That is my experience of him after 15 years' professional work. "A labourer is worthy of his hire" Why not—

A MEDICAL LABOURER?

Nov. 20th, 1900.

THE UNIVERSITY OF BIRMINGHAM MEDICAL DEGREE FOR PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—The recent regulation of the University of Birmingham, whereby registered practitioners who have studied at the School of Medicine there will be admitted to the M.B. examination, will be a very great boon to provincial practitioners.

Some others of us are apt to think that the favour is almost too great a one to bestow for the mere accident of localities and if the Senate of the University could extend the operation of the rule so as to include every registered practitioner who had passed the matriculation examination up to a certain date it would deal in a practical form with a widespread grievance and would ensure some degree of arts training in the graduates.—I am, Sirs, yours faithfully,

Dublin, Nov. 17th, 1900. J. C. MCWALTER, B.A., F.F.P.S. Glasg.

THE CASE OF DR. PATRICK QUINLIVAN.

IN our issue of last week we published an appeal from a committee formed to aid the family of the late Dr. Patrick Quinlivan. The honorary treasurer is Dr. R. Ambrose, M.P., The Mount, Whitechapel-road, E., to whom subscriptions may be sent, and the following subscriptions have been received:—

"THE QUALIFIED QUACK."

To the Editors of THE LANCET.

SIRS,—If you refer to the Medical Register for 1900 you will find that John Harman Tarrant has neither the diploma of F.R.C.S. Edin. nor that of L.R.C S. Edin. standing after his name. He was deprived of these qualifications, I believe, in December, 1899.

I am, Sirs, yours faithfully,

Lancaster, Nov. 16th, 1900. C. W. DEAN.

*** The proper action of the Royal College of Surgeons of Edinburgh had escaped our notice. It remains for the Royal College of Surgeons of Ireland to follow suit.—ED. L.

"UNUSUAL LAPSE OF TIME BETWEEN TWO PREGNANCIES."

To the Editors of THE LANCET.

SIRS—On May 12th (p. 1413), 19th (p. 1481), and 26th (p. 1566), 1900, three communications appeared in THE LANCET giving examples of long intervals between successive pregnancies. Perhaps the following parturition history of a woman whom I attended at her last confinement may prove interesting to some of your readers. She was born in February, 1850, and gave birth to four children as follows:—August, 1867; July, 1868; March 19th, 1870, and Dec. 13th, 1895. It will thus be seen that an interval of 25 years elapsed between her third confinement and her fourth conception, but the occurrence of the latter may possibly be explained by the fact that in February, 1895, she was in hospital for some weeks for the treatment of a urethral caruncle, from which, however, she denies that she ever experienced any inconvenience during coition.

I am, Sirs, yours faithfully,

Old Basford, Nottingham, Nov. 3rd, 1900. A. FULTON.

MIXED.

BEFORE the Middlesbrough stipendiary recently an applicant for an order exempting his infant from vaccination applied for "a separation order," much to the hilarity of the court.

AN OLD MEDICAL ACCOUNT.

WE are indebted to Mr. N. J. Highmore, of the Solicitor's Department of the Inland Revenue, for the following old medical account:—

1776. MRS. ELLEN HADDERTON.
March Dtr. to T. Jeffery.
24th.

	s.	d.
To three purging Potions	2	0
To a Cooling Collyrium	1	3
Ditto repeatd	1	3
Two Blystering Plasters and Dressings pr. Ditto ...	1	6
	£0 6	0

Receiv'd Apl. 27th, 1776, the above in full,

pr. T. Jeffery.

◆

Isolation Hospital.—We do not know of any literature that bears on the subject. An isolation hospital of 60 beds can clearly be run for much less money than can two isolation hospitals of 30 beds each. The practical way of ascertaining the facts would be to write to one or two sanitary authorities having supervision over isolation hospitals of 30 and 60 beds, and ask the cost of maintenance.

C.—It is legitimate to give a reasonable amount of publicity to the change of residence in the manner suggested.

Enquirer, who has not chosen a very distinctive pseudonym, is recommended to consult her medical man.

J. W.—Yes.

ERRATUM.—In regard to the Bradshaw Lecture, THE LANCET, Nov. 10th, p. 1323, the figures for the analysis of urobilin should read thus:—C, 63 58; H, 7·84; N, 4·11; O, 24·47; total, 100·00.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), *Gt. Northern Central* (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (27th).—London (2 P.M.), St Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.)

WEDNESDAY (28th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), *St. Thomas's* (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9 30 A.M.), Gt Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2 30 P.M.), London Throat (2 P.M.) Cancer (2 P.M.)

THURSDAY (29th).—St Bartholomew's (1.30 P.M.), St. Thomas's (3 30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2 30 P.M.), London Throat (2 P.M.), *St. Mark's* (2 P.M.), Samaritan (9 30 A.M. and 2.30 P.M.).

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3 30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9 30 A.M. and 2.30 P.M.).

SATURDAY (1st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the *Royal London Ophthalmic* (10 A.M.), the Royal Westminster Ophthalmic (1 30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (26th).—SOCIETY OF ARTS.—8 P.M. Prof. J. A. Fleming: Electric Oscillations and Electric Waves. (Cantor Lecture.)

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council Meeting 8 P.M. Paper:—Mr. T B Constant: The Etiology of Superior Protrusion. Casual Communications:—Mr. C. V. Cotterell: (1) A Composite Odontome; *(2) A Case of Inverted Eruption of a Tooth.*—Mr. J. G. *Turner*: Pedunculated Epulis and Supernumerary Teeth.—Mr. Perry: The Microscopical Appearances of Teeth removed from a Graveyard. Lantern Display:—Mr. D. Gabell: Multi-coloured Sections of Teeth and other Histological Subjects.

MEDICAL SOCIETY OF LONDON.—8 30 P.M. Dr. F. de Havilland Hall: The Diagnosis and Treatment of Thoracic Aneurysm. The following gentlemen are expected to take part in the discussion—Dr. Barlow, Dr. Beauchamp, Dr. C. Browne, Dr K. Fowler, Dr. V. Harris, Dr. N. Moore, Dr. G. Smith, Mr. Sanderson (Brighton), and Dr. H. Walsham

TUESDAY (27th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Sir Thomas Smith: Suggestions for a possible Improvement in the Method of Removing Stones and Morbid Growths from the Interior of the Bladder.—Mr. W. G. Spencer: Median Perineal Urethrotomy and Cystotomy through a Superficial *Tranverse Incision, after Celsus* *Demonstration*:—Dr. T. R. Bradshaw (Liverpool): An Undescribed Crystalline Urinary Deposit.

WEDNESDAY (28th).—HUNTERIAN SOCIETY (London Institution, Finsbury circus).—8.30 P.M. Pathological Evening

SOCIETY OF ARTS.—8 P.M. Major R. Ross: Malaria and Mosquitoes

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4 30 P.M. Exhibition of Cases 5 P.M. Meeting.

THURSDAY (29th).—CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Prof. C. S Sherrington: Physiology for Teachers.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (26th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr R. Crocker: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr Ball: Examination of the Throat, Nose, and Ear.

TUESDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. Taylor: Consultation. (Medical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—5 P.M. Clinical Lecture:—Dr. P. S. Abraham: Vegetable Parasitic Diseases.

WEDNESDAY (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. B. Cheadle: Consultation. (Pediatrics.) 5-7 P.M. Dr. H. Tilley *Class.* Practical Rhinology and Laryngology.

LONDON THROAT HOSPITAL (204, Gt. Portland street, W.).—5 P.M. Mr. E. B Waggett: Diseases of Accessory Sinuses. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Wethered: Cardiac Dilatation.

THURSDAY (29th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Mr. Voelcker: Diphtheria.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. Holloway: Diagnosis and Treatment of some Diseases of the External Meatus.

WEST LONDON POST-GRADUATE COURSE (West *London Hospital*, W.).—5 P.M. Dr. Abraham: Some Skin Affections.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Wallis: Surgical Cases. (Post-graduate Course.)

FRIDAY (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thomson: Consultation. (Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mr. J. W. Allison, Southsea; Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Mons J. Alcan, Paris; Mons. J. Astier, Asnières, France; A. G. E; A R H.; Dr. H. Anders, Philadelphia

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Harveian Lectures

ON

PROGNOSIS AND TREATMENT IN PULMONARY TUBERCULOSIS.

Delivered before the Harveian Society of London on Nov. 1st, 8th, and 15th, 1900,

By ROBERT MAGUIRE, M.D., F.R.C.P. Lond.,

PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL.

LECTURE I.

Delivered on Nov. 1st, 1900.

Mr. President and Gentlemen,—I thank you heartily for the honour you have done me in asking me to deliver your annual Harveian Lectures. In choosing a subject for them I could not but be influenced by the methods used by the man whose name you have chosen to designate this society and these lectures. He trusted especially to observation and made theory subservient to this. Bacon's maxim of "Hypotheses non fingo" is said to be wrong, and taken literally no doubt is wrong. Newton, finding, as it is said, his facts after his theories, did good work and his method has been followed by some in our profession with success but only by few. Yet Newton first saw the apple fall before he reasoned from that fact, and therein he followed the Baconian method. Again, let us remember that Newton dealt with very simple sciences—only with astronomy, physics, and chemistry—nature in its normality, however complex that normality may be, and from normalities one may comparatively easily be led to certainties as, indeed, Newton was. We on the other hand have to deal with nature in its abnormality, a vastly more complex science in which theories must be outside our knowledge until facts—much more indefinite than the fall of Newton's apple—are carefully observed. Let us start then by recording our facts in the way Bacon did, in which Newton actually did, though he is said to have pursued another process in his reasoning, and in which Harvey combined the methods of both. Let us only very carefully suggest theories after facts have been well observed and try not to go beyond those facts.

I wish to present to you facts and then conclusions from those facts. Therefore I have chosen a subject upon which I can deal with facts from a somewhat large experience, and can give you the conclusions which I myself have been able to draw from them. Thus I have taken as my subject, Prognosis and Treatment in Pulmonary Tuberculosis, and yet let me at once say that I do not intend to deal with the whole of these subjects. To do so would lead me beyond our three lectures and would cause me to tell you many things which you know already and others which you can just as well read in the text-books or in the journals as you can learn from me. I wish only to give you points which I have learnt myself from experience and to ignore, as far as possible, those which I have learnt from others, as you also can learn them from others. I appeal for my facts especially to the records of the large number of patients intrusted to my care at the Brompton Hospital for Consumption and Diseases of the Chest, in the out-patient department, later to those of the in-patient department, and to others seen elsewhere. Again, I have made use of the records of the post-mortem rooms at the Brompton Hospital, at St. Mary's Hospital, and at the Manchester Royal Infirmary during the periods in which I was pathologist to those several institutions, while finally, I will give you facts from experiments on animals and upon myself mainly relating to a new method of treatment of pulmonary tuberculosis, which will be described in my third lecture. There I will describe how I have taken advantage of Harvey's great discovery, the circulation of the blood, and, as I hope, for practical advantage in the treatment of disease. Such conclusions as I have been able to draw from the facts I will offer for your consideration, but I intend to make no inferences which the facts cannot reasonably warrant.

Prognosis ought to be based upon full diagnosis, that is, not the mere naming of the disease, but a knowledge of its nature and its course, and a power of appreciating the tendency of such course, and of the signs which indicate its progress. Prognosis sometimes seems to come to a man by instinct, or by what my late and most revered master, Sir William Roberts, used to call "clinical acumen." Some men, and only few, have this power, but even such persons it has always appeared to me, arrived at their results from unconscious observation and reasoning. They would tell you that a certain course would be pursued by a certain case of disease and that they did not know why they thought so, yet such men have always had keen observation and, unknown to themselves, have reasoned from observed facts. For the majority of us to trust to any such instinct would be fatal to our conclusions, and we ought therefore carefully to reason only from well-observed facts.

Let us then, apply the method I have mentioned to the prognosis and treatment of pulmonary tuberculosis, understanding by this disease, not all the cases which are vulgarly called 'phthisis' or 'consumption'—though we may by accident occasionally lapse into the use of these terms—but only those affections of the lungs which are accompanied and caused by the presence of the bacillus tuberculosis. And yet let us also remember in estimating our prognosis and in considering our treatment that the tubercle bacillus does not perform its noxious work alone but is aided by at least two other germs, the staphylococcus pyogenes, causing suppuration, and the pneumococcus causing pneumonia, and each, together with the tubercle bacillus causing poisoning of the general system by its own scarcely yet recognised product. We must then consider pulmonary tuberculosis, as seen clinically, to be a product of all these three germs, and we must form our prognostic opinion and our therapeutic methods upon observation of the effects which each or all of these germs has produced upon the lungs or upon the general system at any particular time.

We hear occasionally of a pre-bacillary stage of phthisis. This no doubt exists but with it we have here nothing to do. We have been accustomed also to divide the conditions of pulmonary tuberculosis into three stages according to their clinical manifestations and to speak of (1) consolidation, (2) softening, and (3) cavitation—names useful enough in their way, but conveying not much to the mind beyond the condition of physical signs which causes their discovery.

Let us, for the purpose of prognosis, think again of three stages, similar to those already mentioned but described rather in view of the pathological conditions which we know, or ought to know, are accompanying them, and we may style these stages, in view of the progressive action of the tubercle bacillus and its companions, (1) invasion, (2) progress, and (3) result. In each case we suppose the tubercle bacillus to be the main noxious germ but, except after the quite early period, to be accompanied by the staphylococcus and pneumococcus. Further, the second stage in one part of a lung may undoubtedly be accompanied by the first stage in another neighbouring or remote part and the third stage, "result" or destruction of lung tissue, may be accompanied, similarly, by both the former stages.

Still another factor must be considered in our prognosis and that is the resistance of the lung and general body powers to the invasion of the bacillus—a most important matter, for by it many apparently pneumonic processes may be caused, and these may be not unhealthy but curative—'chemiotaxic,' as they are called.

All these points must be considered in forming a prognosis and we must discuss them in certain of their aspects under these several headings.

And yet still something else must be defined before we approach the subject proper and that is what we ought rightly to understand by prognosis in each of the above stages of the disease. In the first stage, that of invasion, we wish to attain to complete cure of the patient, an absolute arrest of the bacillary invasion and a return of the lung to an entirely normal condition and yet with the same tendency to reinfection which previously existed, a tendency innate in the subject. That tendency having once shown itself, perhaps being recognised for the first time on the outbreak of the lung trouble, may be combated by suitable means but for a long period must remain hanging over the patient. Such is the most favourable result to which we can attain by the use of all remedies at our disposal, and its probability we style a "favourable prognosis."

are the more likely to present latency of the physical signs, which, as I have above pointed out, is of grave significance. On the other hand, the anæmic subjects much more commonly have shown a slow progress of the disease. Yet in estimating the prognosis one must think, too, of the effects of treatment in such cases, and certainly one finds that the florid patients, when once got hold of, are more amenable to the ordinary methods of treatment than are the anæmic ones. To summarise the above remarks I would say that, viewing the much larger number of anæmic than of florid patients who are attacked by pulmonary tuberculosis, the percentage of cures and of slow progress of this disease is very much greater in the anæmic than in the florid. Given that a florid person is really attacked by pulmonary tuberculosis and that this is decided by perfect observation, the prognosis of his case is on the whole more serious than is that of an anæmic person similarly attacked. An explanation of this may be found in a remark of Sir William Broadbent in his book on "The Pulse," that such florid patients are generally the subjects of vaso-motor atony.

Deformity of the chest undoubtedly predisposes to tuberculosis of the lungs, and this, too, whether the deformity be due to simple scoliosis or to kyphosis from pre-existent tuberculosis of the vertebræ. From whatever cause the deformity results, it greatly increases the gravity of the prognosis when once tuberculosis of the lungs has established itself. This has an obvious explanation. The deformity interferes with respiratory movement and hence with the circulation of blood through the lungs. The tubercle bacillus has then a better chance of attacking the lung tissue without the protection of the tissue by a free flow of nutrient blood. The result is almost invariably, as I have found, a rapid destruction of lung tissue and also an even more rapid decrease of the body powers consequent upon the general feeble vitality. The prognosis is bad. Such deformity of the chest is often, as I have mentioned, due to an actual tuberculous disease of the vertebræ, and this leads one naturally to the consideration of other pre-existent tuberculous affections, and especially to the prognosis of tuberculosis of the lungs following and accompanied by tuberculosis of the lymphatic glands. Before the nature of the pathological process in such glands was accurately known the condition was described as the scrofulous diathesis, and undoubtedly the patients who suffer from it constitute a group differing greatly in many points from those whose lungs are affected at the beginning of their disorder. What is the essential difference between these two rough groups I do not know, but that there is such difference I am well aware of. The danger to a patient of possessing such tuberculous glands is certain. Nevertheless, judging from my own experience, I must say that the progress of a pulmonary tuberculosis secondary to a pre-existent glandular affection is much slower and consequently more favourable than when the lung tissue is primarily invaded. The glands, we know, form a resting-place for the tuberculous poison, a resting-place fairly well cut off from the rest of the body by hardened inflamed tissue, and, still more important for the purpose of prognosis, a resting-place which can often be easily removed together with its contained poison. The surgeons now deal freely with such glands, and absolute ablation is the best remedy for them. The possibility of this greatly increases the probability of cure of any lung affection which may accompany them. They can also be removed by other means, but, to trench upon the subject of my later lectures, let me at once say that nothing can be worse for the future of the patient than the so-called dispersal of such glands by painting with *iodine* or *rubbing with iodide* liniments. The glands then may disappear, it is true, but very frequently only to spread their contained poison elsewhere in the body and to increase any lung trouble which may exist. I shall eventually have to mention how such glands can safely be dispersed, and in a marvellous manner, by the administration of nuclein by the mouth, and then without such bad effects as I have mentioned. But the presence of such glands seems to me to be, on the whole, a favourable element in the prognosis of a tuberculous lung affection in that they can be usually easily removed, that their removal takes away an important focus of tuberculous poison and leaves the lung tissue unhampered in its efforts to fight the bacillus, and, lastly, that the diathesis, if we must call it so, which is displayed by such lymphatic tuberculosis, is generally combined with a similarly slow process of tuberculosis in the lungs.

Time will not allow me to do more than merely hint at the influence of the presence of lymphadenomatous glands and also of lymphadenomatous and malignant disease of other structures upon the progress of a tuberculous disease of the lungs. Suffice it to say that the combination is uncommon and the gravity of the more or less malignant disease entirely overshadows that of the tuberculosis. The connexion of the two series of disorders, uncommon as it is, is extremely interesting, and the out-patient department and also the post-mortem room at Brompton Hospital have given me matter which might well be discussed, but almost entirely from the pathological and not from the clinical standpoint. Again, too, I will not deal here with the co-occurrence of cardiac disease and tuberculosis of the lungs, or their mutual affection of the prognosis, for this has been treated very fully by others.

But amongst the most important disorders (from the prognostic point of view) which may precede an outbreak of tuberculosis of the lungs are pleurisy, serous or purulent, and pneumonia. I have already mentioned how serious is the outlook when pulmonary tuberculosis first shows itself by the presence of scattered patches of pleurisy. I do not wish to refer here to this particular form of outbreak, but to those cases in which a pleurisy, generally with effusion, precedes the onset of the tuberculosis. It is, nevertheless, remarkable how often, judging from the results of many observers, an apparently simple pleurisy with effusion is really tuberculous in nature, as evidenced by the finding of tubercle bacilli in the exuded fluid. Yet we know very well how comparatively seldom such a pleurisy with effusion is followed by more general pulmonary tuberculosis, and I would especially call your attention to this fact as giving ground for the belief that simple pleurisy with effusion need not necessarily bear with it a bad prognosis for a tuberculous subject. Undoubtedly, a pleural effusion, not previously ascertained to be tuberculous, is in some instances followed by an outbreak of tuberculosis in the apex of the lung of the same side, and probably this is due to malnutrition of the lung consequent upon its disordered circulation. But from actual observation I can say that such outbreaks of tuberculosis are rarely so serious in their actual attack or in their further progress as those which have not been preceded by such an effusion. Again, departing somewhat from our order of discussion, I will mention here that the occurrence of pleural effusion in the course of a pulmonary tuberculosis, and especially in the stage of invasion, seems to be actually of benefit if only that effusion be not removed. It is well known at the Brompton Hospital that a simple pleural effusion in a tuberculous patient is best left alone if it does not seem to be unduly hampering the respiratory apparatus, and a probable explanation of this fact I will give under the head of Treatment.

When the pleuritic fluid is not serous but purulent, when, in fact, an empyema has occurred and has been removed by operation, it is again remarkable how seldom this is followed by pulmonary tuberculosis if we take account of the large number of cases of empyema which come under treatment and are permanently cured. Yet when tuberculosis does break out after empyema its course is usually rapidly fatal, a result which one might expect from the fact that the original empyema is itself the result of a very low vitality, and this will of course have its due influence upon a following tuberculosis.

Pneumonia is an essential element of pulmonary tuberculous outbreaks, and, indeed, gives rise to nearly all the physical signs from which we form our diagnosis. But we at this point must deal with pneumonia as a precedent of the outbreak—a pneumonia not of itself tuberculous, but occurring in a person predisposed to tuberculosis. I am not much afraid of a tuberculosis of the lung which follows upon an ordinary croupous pneumonia. But I must be careful here to make myself perfectly understood. I am speaking of the prognosis of the tuberculosis and not of that of the pneumonia. Naturally, tuberculosis is a danger to a person who is suffering from croupous pneumonia and its possible outbreak greatly increases the gravity of the prognosis of the pneumonia. But I think the previous existence of a simple croupous pneumonia does not materially affect the prognosis of a consequent tuberculosis. Most croupous pneumonias affect the base of the lung and tuberculosis consequent to them is, as I have already stated, not only rare, but slow in progress. Pneumonia affecting the apex of the lung, beginning in the ordinary turbulent way of the croupous affection and not initially tuberculous, if it does not cause immediate death, is generally followed by complete resolution of the lung, and, indeed, more frequently and completely than the same affection of the base. The pneumonias of the base which are followed by tuberculosis of the same part are much more frequently found in children, and for this reason, too, the prognosis is the more favourable.

I would say a few words about tuberculosis of the urinary organs followed by tuberculosis of the lungs. 'It is curious that urinary tuberculosis, beginning as such should remain for so long a time—and this is a fact in its history—located to the urinary organs alone.' This seems to be the case, no matter where such urinary tuberculosis first shows itself, whether in the kidney, the ureter, the bladder, the urethra, or the *vesiculæ seminales*. Probably, it seems to me, the reason can be found in the fact that the urinary organs are mostly developed from a different embryonic layer than are the lungs and most other of the internal organs. Yet towards the end of such cases one does meet with pulmonary tuberculosis. Invariably, I have found that the lung trouble plays only a very minor part in causing the end of the patient—the pulmonary tuberculosis, as such, bears a favourable prognosis. Unfortunately, this is of not much benefit to the patient, for by the time the lung trouble has developed his condition is otherwise hopeless.

My out-patient records afford some evidence too of the effect on prognosis of previous tuberculous disease of the lungs in the same family, though let me say that I inquired only into the history of father, mother, brothers, and sisters. Incidentally they indicate how rarely such tuberculous family history could be obtained if we take into account the large number of tuberculous cases included in the records. This supports the view held by modern hygienists that heredity does not play so important a rôle in the causation of tuberculosis as does actual infection. Yet the influence of such hereditary tendency can by no means be ignored, for I find that whenever present it very seriously affected the gravity of the case.

Another point, too, which crops up in the examination of this long series of cases is that but few of the patients affected by tuberculosis led open-air lives, and although I cannot actually bring statistics forward to prove this point, yet it was my impression that those exposed to inclemencies of weather, such as navvies, bricklayers, and so on, did far better than did those who had the opportunity for keeping indoors. I lay, however, but little stress upon this observation, for obviously such as had those occupations were the more robust of the patients. And in contradiction to the apparent conclusion let me say that a certain number of my patients were Polish Jew tailors from the East-end, nearly all of them in a terrible condition of poverty and dirt, and living, as we know, with the most frightful unhygienic surroundings. Only few of these had tuberculous affections, but they suffered greatly from bronchitic and other catarrhs.

A Clinical Lecture

ON

THE TREATMENT OF CERTAIN CHRONIC ABSCESSES BY SIMPLE ASPIRATION.

Delivered at St. George's Hospital on June 19th, 1900,

BY WILLIAM H. BENNETT, F.R.C.S. ENG.,
SENIOR SURGEON TO THE HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

GENTLEMEN,—In advanced days like the present a surgeon who deliberately recommends the use of a treatment which is commonly considered old-fashioned or out of date necessarily places himself in a somewhat dangerous position, since he is liable to be thought either to have lost touch with the spirit of the times or to lack energy and resource to keep abreast with the progress of recent affairs. For my own part, however, I am sure that with an audience like the present, well acquainted with my ordinary practice, I run no risk on this account, and if I run any such risk with others less familiar with me I am content to accept it, because I believe it is only by the record of long personal experience that the value of any treatment, whether new or old, can be properly estimated. Further, it must be remembered that some old-fashioned methods in surgery which failed to achieve ends which would now be considered good, under our present system of cleanliness effect results which, if not ideal, are at least extremely satisfactory. My purpose to-day, then, is to call your attention to one of these old-fashioned methods—viz., the treatment of certain chronic tuberculous abscesses by *simple aspiration*.

Thirty years ago or thereabouts the aspiration of abscesses was a very common method of treatment. At that time the antiseptic system, although spoken of, had not come into vogue and the practice which we now adopt of immediately treating almost every abscess which comes under observation by free incision did not hold good, because treatment in that way was generally followed, at all events in large abscesses, by extremely high reactionary fever, septicæmia, or pyæmia, so that no prudent surgeon as a general routine would have adopted the treatment. Hence it came about, especially in psoas abscess and in abscesses about the hip joint in connexion with tuberculous disease, that the alternatives presenting themselves to the majority of surgeons at that time were aspiration, opening by a small incision, or allowing the abscess to burst. To those of you who do not know the state of surgical treatment in those times it may sound strange to hear that patients with abscesses about the hip, with psoas abscess, or with large collections of pus in other parts would sometimes be allowed to lie in bed for months waiting for the abscesses to burst. Finally, during some night or day (it was generally at night) the abscess would burst and the bed and the patient would be flooded with pus. That was not an uncommon treatment by some surgeons of such chronic abscesses connected with bone disease, especially of the hip and spine. Mr. (afterwards Sir) Prescott Hewitt, who was then senior surgeon to St. George's Hospital, had quite a reputation in the treatment of abscesses of this kind. He almost invariably allowed them to burst and, speaking generally, his cases progressed more favourably than was the average at that time. I have said that the reason that these abscesses were allowed to burst was that if they were incised severe septic fever nearly always followed, the majority of patients dying ultimately from "hectic fever," or from some other form of blood-poisoning the result of septic absorption. It was supposed that the patients in whom the abscesses were incised did so badly because the fresh cut surfaces made by the knife afforded an easy means of entry for the poison into the blood. It was said, on the other hand, that if the abscess was allowed to burst the vessels, mainly the veins, by which the poison entered the blood were sealed in the process and so blood-poisoning was less likely to occur. By many surgeons, therefore, these abscesses were allowed to burst, and those which burst certainly, as a rule, did better than those which were opened. This method was, however, always a very unpleasant and frequently an unsatisfactory one. In consequence aspiration—i.e., the emptying of these abscesses by successive tappings with the aspirator—became a common practice. The aspirator in its present form is not a very ancient instrument—indeed, it was first brought into use at this hospital about the time when I was house surgeon, from 1874 to 1875. Before that time the aspirator as you now see it was practically unknown. At that period, although it was before the antiseptic era, surgeons had learned to realise the fact that if a cavity in the body containing fluid could be emptied without admitting external air the results were generally better than when the external air entered the cavity; in other words, that a large number of abscesses which were treated by aspiration, even if they were not cured, became by degrees very much smaller without any constitutional disturbance, so that an abscess (psoas, for example) which originally might have contained a couple of quarts of pus would dwindle down, after successive aspirations, until it was hardly perceptible. Hence aspiration was not only useful because it sometimes led to the complete cure of an abscess, but also because, failing a cure, it was obviously more satisfactory to open an abscess containing a very small amount than one containing several quarts of fluid. Unfortunately, however, these good results were not the rule, for it was frequently found that "suppurative fever" followed aspiration necessitating the free opening of the abscess—a treatment which more commonly than not in large abscesses, like those associated with disease of the spine or hip, finally ended in death from pyæmia or septicæmia. That this should have been so is not remarkable, as no adequate cleansing of instruments at that time was used.

I have, indeed, seen the aspirator needle taken from one abscess and almost directly, without a more thorough cleansing than a dip in cold water and a rub with a towel, plunged into another patient. In spite of these results, however, the aspirator was then looked upon by many surgeons as better than the knife.

In these days of well-understood surgical cleanliness there is, of course, no reason why the introduction of a properly sterilised needle or trocar into an abscess should be followed by any harm at all. Speaking generally, there is no doubt that the best treatment for chronic tuberculous abscesses is free incision and scraping followed by immediate suturing of the wound, or drainage, as the case may be; but it is extremely difficult to insist with safety upon the use of a routine method of this kind under all circumstances, and there is, I fancy, hardly a single well-tried routine method which is not sometimes amenable to modification with advantage. I think that if you consider for a moment the position of some practitioners and the conditions in which they have to practise their profession you will see that it cannot always be to the advantage of the patient or of the practitioner that chronic abscesses of large size—say, for example, of the thigh—requiring an incision of perhaps six or eight inches in length, in order that their contents may be thoroughly scraped away, should be dealt with in this manner. Conceive yourselves for a moment in the position of a practitioner working amongst poor people setting about a case of this kind in squalid insanitary surroundings with inadequate means for obtaining asepsis and all the difficulties with regard to dressings and time which must frequently arise under such circumstances. A moment's reflection will show that, however safe the radical treatment may be with those who have all the appliances and advantages which a great hospital like this provides, it cannot be undertaken with anything like the same chances of success by practitioners working under the condition just indicated. To such the aspirator is an instrument of the greatest value. The following cases will serve to illustrate the occasional advantages of this method of treatment.

CASE 1.—There is now a female patient in the Wellington Ward of this hospital, aged 26 or 27 years, whom I have treated in the way I have described. Some years ago she suffered from acute hip disease of tuberculous origin; ankylosis followed upon the usual treatment, and, the limb being in a good position, she could walk well, but of course she limped considerably. Unfortunately, she was not content with her condition. She resented the stiffness of the hip and longed for some power of movement in it. She therefore sought advice with a view to getting the movement which she so much desired. The result was, it appears, that an anæsthetic was given to the patient and the joint was freely broken down. The effect of that procedure was to give her some mobility for the time being which, of course, pleased her much. But the effect, also, after a little time, led to the formation of an abscess round the hip—a "quiet" abscess, which caused little pain but rapidly increased in size. On her admission she was in a very delicate state; she was feeble and very nervous and excitable. The temperature was normal and there was little, if any, pain. Over the left hip joint was an abscess which extended from the anterior superior spine of the ilium downwards to within three and a half inches of the knee, involving about one-half the circumference of the thigh. Some treatment was urgently called for and the question arose as to the best method to pursue. As I have already said, the patient was very delicate. The abscess was very large, but there was no high temperature or anything to show that there was acute inflammation proceeding, but there was this growing collection of fluid. The ordinary treatment would obviously have been to lay the abscess open from end to end and to scrape it freely out, but this would have necessitated an incision from the anterior superior spine of the ilium to within about four inches, or at all events to within five inches, of the knee joint—a very extensive operation for a patient in her condition. There came, therefore, the question whether there was any milder plan which could be adopted, at all events temporarily—some treatment which would not at the time subject her to the same danger as would be run in the very free laying open and scraping of this great cavity. Here, it seemed to me, was an opportunity to try the alternative which I mentioned just now—namely, aspiration. I can well imagine some of my more energetic juniors thinking it hardly conceivable that any up-to-date or possibly even any competent surgeon could recommend such a proceeding in the present day. Nevertheless my experience told me that its trial in this case was right and so we adopted it. What has been the result? I tapped the abscess with the aspirator, and on the first occasion we drew off a very large quantity of fluid which was allowed to flow freely until it had become slightly blood-stained, when the trocar was withdrawn, the small opening made by it being sealed with collodion. After the withdrawal of this fluid there was very little evidence of the existence of the abscess at all, except that the side of the thigh was flabby and somewhat puffy. The sense of fluctuation and all the other signs of an abscess had disappeared. In the course of a fortnight the abscess had filled again to half its former capacity. It was tapped again, and this time very much less fluid was drawn away. We tapped it a third time and, later, a fourth time, at intervals of 10 days and a fortnight. After the fourth aspiration no fluid could be got to flow through the cannula and there remained a doughy tumour on the outer side of the thigh not more than a quarter of the size of the original abscess. I concluded therefore that in the course of our tappings we had withdrawn practically the whole fluid contents of the abscess. What was left was granulation and fibrous tissue around the abscess cavity. Having got to this stage I have no doubt that if we could have afforded to keep the patient in the hospital long enough, and if she had been content to wait, the process of inspissation would have taken place, and that in all probability the abscess would have dried up altogether without any further interference from the surgical point of view. Time, however, especially in these hospital cases, is of value, and as I thought that we could now deal with the abscess through an opening about one-third of the size of that which would have been required in the first instance I laid the cavity open by this comparatively small incision and cleared out what was left of the abscess contents. Upon opening the cavity there was a little oily fluid, but very little, and in fact the whole operation was more like the removal of a soft solid tumour than like dealing with an abscess. The cavity had contracted down to a great extent until it was less than one-third of its original size when the patient was admitted to the hospital.

As you have without doubt noticed, this is not a case which illustrates the *cure* of an abscess by aspiration, and on this account I have taken it as my first illustrative case because it shows very well how, under certain circumstances, if you choose to use this treatment discreetly the radical operation may be reduced from a measure of great severity to one of comparative slightness, a very important matter to a patient in the condition of this woman.

The following is an instance showing how a complete cure is sometimes brought about by this treatment.

CASE 2.—The patient was a very busy man, who was not only much occupied at home but was constantly travelling over all parts of Europe on affairs of business. He had hip disease when he was a boy. He is now approaching 50 years of age. The hip disease was followed by firm fibrous ankylosis in a position which at first was not good. The faulty position was, however, rectified later by tenotomy (about 22 years ago). I remember the details of his case well, because I gave the anæsthetic at the time of the performance of the operation. I saw nothing of the patient after this until about a year ago; there was therefore an interval of more than 20 years between the time when I gave him the anæsthetic and the time of my seeing him the other day. He had been perfectly well in the meantime but about a year ago he began to feel a little discontented because he felt a band at the inner aspect of the hip which seemed to drag a little at times. Being a man of a mechanical turn of mind he naturally argued that if that band were divided he would be very much more comfortable, and, further, he thought that he would get a little more movement in the hip, so he came to me with a view of having this band divided. (In passing, I would ask you to bear in mind what happened to the patient whose case I have just described. She was not content with the position of her limb, and although she had a perfectly sound stiff hip she wanted movement. The hip was broken down and freer movement followed for a time—at the cost, however, of the development of the large abscess on account of which she came to the hospital. Now, if there is one thing more important than any other which you must bear in mind in all cases of tuberculous disease affecting joints, I do not care what the joint is, it is this: ankylosis having become firm, although all signs of active disease may have been gone for years, it is a dangerous thing, speaking generally, to attempt to get a moveable joint in such cases by breaking down or otherwise interfering with the actual line of union. In almost all tuberculous cases which heal in this way there is left a certain amount of what may be called latent tubercle; I mean little caseating masses which, if they are disturbed, will, as often as not, lead to the lighting up of fresh disease, ending in the formation of these abscesses which are so frequently seen in tuberculous joints which are interfered with in this fashion. There is no condition, I suppose, to which the old motto, "Let sleeping dogs lie," applies with more force than "quiet" or "cured" tubercle. Never disturb quiescent tubercle if you can help it. An excellent warning of the same kind has occurred in this hospital in the case of a boy on whom I operated to-day for tuberculous peritonitis. He came to the hospital some few weeks since with inguinal hernia which required operation. At the time of the operation upon the hernia a caseous mass was revealed in the cord adherent to the back of the sac. As a matter of necessity the mass had to be removed. It was latent caseating tubercle—"cured" tubercle, in fact. Although the little fellow was perfectly well previously in general health as far as he knew and as far as we could see, except that he had rather a large abdomen, almost before the wound of his hernia had healed he developed rapid tuberculous peritonitis. My belief is that if the latent nodule of tubercle in this case could have been left without interference at the operation I should not have had to operate on the boy this morning for tuberculous peritonitis. The stirring up of the quiet focus started a fresh tuberculous invasion. I mention this case with the other because it shows so well the danger of disturbing quiet tuberculous conditions.) Returning to the case of the patient whom I was describing you will remember that the tense band of which he complained was a source of great annoyance to him; nevertheless, nothing would induce me to interfere with it because of the danger which I believed would be run in the proceeding of lighting up anew quiescent disease. Moreover, I was by no means sure that the recent sense of irritation was not already due to a recrudescence of the old disease in a small way. This suspicion of mine was subsequently justified, for about eight months afterwards the patient came to me again, rather satisfied with his condition because he found that he had a little more movement than before. He stated that he had been "working away at the band" as much as he could, and he demonstrated with some satisfaction the progress which he had made towards increasing the movement at the hip. "In addition to this," he said, "the muscles about the outer side of the hip are really getting quite full and hard." I examined the parts: there was certainly a little more movement at the hip, but the "hard muscles" thought to be felt were in reality the swelling of an abscess. In fact, a large abscess had developed which was so quiet in its progress that the patient was unconscious of its formation. It extended completely across the thigh just below the hip, so that percussion on the outer side of the thigh conveyed a distinct sense of fluctuation to the finger placed on the inner side. It was most important in this instance that the patient should not be laid up. I gave him my opinion of the case, at which he was naturally disheartened. I also told him what the ordinary treatment would be. Under the circumstances in which he was placed, which were such as to make laying up at that time almost impossible, although it was plain that something must be done, it was at the same time manifest that to open an abscess containing at least a pint or a pint and a half of pus, the patient at the same time being able to continue his occupation, was quite out of the question. I therefore treated the abscess by aspiration. At the first tapping one and a half pints of pus were drawn off. A fortnight later, the abscess having re-filled to half its former size I tapped again. At various intervals I emptied the abscess five times, never allowing it to attain more than half the size which it had reached at the previous tapping; at the last tapping only three or four drachms of pus could be withdrawn. That is now some seven weeks ago. There has been no reappearance of the abscess, the patient is absolutely well, and at the present time there is not the least indication of an abscess having existed. The treatment, extending over about three months, was carried out without interrupting his work for a day. There is no other plan which, so far as I know, could produce such a result with so little inconvenience and trouble to the patient.

CASE 3.—The patient, a female, 27 years of age, noticed a gradual enlargement of the left hip for which she could not account. No injury had been received and she was, so far as she knew, in perfect health. The enlargement by degrees assumed the character of a distinct tumour about which she did not much concern herself until an aching pain was habitually felt after a long day of standing or other exertion. As this pain increased steadily she sought advice. Upon examination she appeared to be a strong and healthy young woman. The left hip was enlarged; above and around the trochanteric region there was a well-marked tumour which upon inspection only was suggestive of a lipoma. Upon palpation, however, fluctuation was easily detected and the condition was obviously a chronic abscess. The hip-joint was healthy and no cause for the disease was apparent. The usual treatment by free incision was advised, but to this she would not consent until all other plans had failed, as the laying up which would have been necessary was, under the circumstances in which she was placed, a very serious matter. I therefore thought it worth while to try the aspiration treatment. At the first tapping about two pints of laudable pus were removed. In a fortnight, the abscess having become again half full, it was emptied; ten days later a third aspiration was made; and three weeks after this a final tapping removed about three ounces of pus. No further accumulation occurred and two months later nothing abnormal beyond a slight induration above the trochanter could be detected. When last heard of, eight months after the first tapping, the patient was perfectly well in all respects. Although I could quote other instances, several being cases of psoas abscess, which have been cured by aspiration in the manner which I have described those already mentioned are, I think, sufficient by way of illustration.

I have no desire that you should for one moment suppose that I recommend the adoption of aspiration as a routine method in cases like those described, or that in a general way I think it should supplant other more radical plans. All I wish you to understand is that certain cases of large chronic tuberculous abscesses can be cured in this way, and some, although a cure may not follow the method, may be so modified that the operation finally necessary for their treatment becomes comparatively slight. In abscesses arising from tuberculous disease of lymphatic glands aspiration is not to be recommended under any circumstances, judging, at least, from my own experience, for although I have in this way cured abscesses connected with tuberculous bone disease, &c., I have never, to the best of my belief, effected a cure by the method in lymphatic gland disease. With regard to the details of the treatment there is little to be said. Absolute surgical cleanliness must, of course, be observed in the preparation of the part to be operated upon and in the condition of the instruments. After this the essential points are (1) to be careful to cease to withdraw the abscess contents the moment any sign of blood shows itself in them; and (2) not to allow the abscess to regain more than half its former size before aspirating again. This applies not only to the original tapping but also to the recurrent ones. The more slowly the fluid is withdrawn the better.

It may, perhaps, be new to some of you to hear that very large abscesses, especially of the "psoas" kind, sometimes disappear spontaneously. In these days it is unlikely that you may have the chance of seeing any case of the sort, but in former times, when patients suffering from psoas and other large chronic tuberculous abscesses were kept lying on their backs for many weeks or months without any active measures being taken, it was not regarded as a remarkable thing for an abscess to dry up ("inspissate" was the term used) and disappear. Four or five years ago I had a patient in the Grosvenor Ward in this hospital in whom a large psoas abscess, just as we were about to open it, commenced to diminish and finally disappeared. I have already mentioned this case when lecturing. The patient was a man with a well-marked angular curvature; he is, I believe, at the present time following his occupation. This is the most recent case which has come under my immediate observation. I have, however, a vivid recollection of a case of psoas abscess occurring in the practice of a late colleague of mine in which radical interference was strongly urged but declined by the patient's friends, in spite of the gloomy possibilities which were held out for their contemplation if matters were allowed to take their course. The case, however, although tedious, proved uneventful, for in the course of six months gradual diminution, and finally entire disappearance of the abscess, followed—a result which was claimed as a supreme triumph for domestic surgery. It may be pardonable to remind you that the spontaneous disappearance of abscesses is brought about by the gradual absorption of the fluid contents leading to inspissation; the treatment by aspiration imitates this sometimes natural process and is therefore based upon perfectly rational grounds.

You have without doubt noticed that I have spoken only of simple aspiration without the injection of iodoform or any other germicide. In the commonly used text-books and in other places will be found recommendations, sometimes very strong, for the use of iodoform injections, mainly in the form of emulsion, in all tuberculous abscesses. A fair trial of the drug in this relation led me some time since to the conclusion that no obvious advantage arises from its use. Indeed, I am one of those who rarely use iodoform for any purpose. In operative work I never use it—a fact which is familiar to those who have seen anything of my practice. It may, indeed, be known to some of you that my first admonitions to a house surgeon coming freshly to my work are that he shall be careful about absolute cleanliness and that the use of iodoform shall not be a routine treatment with him. For my own part, I feel bound to say that although I have seen harm come from the use of the drug I have never seen it effect any advantage worthy of mention in operations in any part of the body. In certain stinking or phagedænic sores of a venereal sort it may at times be used with benefit, but in operative work properly conducted it is, in my belief, valueless. On the other hand, I have seen undoubted instances of poisoning from it, and I have seen cases in which, to the best of my judgment, grave complications have arisen solely in consequence of the employment of iodoform. The indiscriminate use of the drug has without doubt vastly diminished of late, but even now by some surgeons, operations, however clean, are rarely completed without its application. For example, the wound in the abdomen after the removal of an appendix during the quiet stage is by some filled with iodoform; the wound resulting from the removal of a breast is frequently freely dusted with it; and I have actually seen the drug freely sprinkled over the parts after an operation for hare-lip. Personally I find it difficult to understand why a drug the germicidal qualities of which cannot be trusted until it has been sterilised in order to kill its own peculiar micro-organisms should be accorded a respect which with some of us exalts it almost to the position of a fetish. Of the evil effects of the drug I could give you sufficient examples were not the matter beyond the scope of the present lecture.

Returning to the main subject which is before us, let me repeat that I wish it to be distinctly understood that I have no desire to advocate the indiscriminate use of aspiration in chronic abscess to the exclusion of the more scientific treatment by free incision and scraping. All that I am anxious to do is to point out that aspiration, in the manner which I have indicated, offers a means of dealing with certain chronic abscesses, especially of the "residual" kind, which can be with safety carried out when the treatment by incision and scraping from the circumstances of the patient, and possibly of the practitioner, is extremely undesirable, if not actually dangerous; and further, that in many cases the aspiration treatment can be adopted without interfering with the patient's ordinary vocation for a single day—an advantage the importance of which in some cases can hardly be over-rated. It is, moreover, a method which offers but trifling difficulty in the matter of sterilisation and needs no complicated dressings or other troublesome details—facts which to those who have to practise, as some of you may have to do, in circumstances of difficulty in the matter of antiseptics and of hygiene, must be of great moment. In this respect it may not be amiss to remind you that it is impossible for all of us, much as we may desire to do so, to practise amongst the wealthy and in the advantageous conditions which can be afforded by riches, or to have at hand the means which are available in a great general hospital like this. To those whose practice lies in the less advantageous circumstances I can with confidence recommend the method as one which, although it may be "old-fashioned," may be used with safety when more radical means are so difficult as to be almost impossible with due regard to the patient's welfare; and further, I am sure, no matter what the facilities of the practitioner may be, that there are many cases of the kind of which I have been speaking in which the use of the aspirator with discrimination may prove of incalculable advantage.

ON A METHOD OF MEASURING THE BACTERICIDAL POWER OF THE BLOOD FOR CLINICAL AND EXPERIMENTAL USES.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

WHATEVER may be the exact rôle played by the bactericidal substances of the blood and lymph in connexion with the destruction of bacteria in the animal organism there can be no doubt as to the important influence which these substances must exert. The quantitative study of the variations in the bactericidal power may therefore serve quite well to elucidate many pressing questions. In the first place, it may furnish valuable data upon which to base a diagnosis and prognosis in cases of specific fever. Again, the quantitative study of the alterations in the bactericidal power of blood which are produced by the addition to that blood (*in vitro* or *in vivo*) of a particular "therapeutic serum" may quite well yield important information with regard to the utility or otherwise of the particular "remedial agent" in question. Furthermore, in the case of animals inoculated with particular bacterial vaccines, a comparison of the bactericidal power of their blood subsequent to inoculation with the bactericidal power of the blood anterior to inoculation may quite well afford valuable indications as to the presence or otherwise in the bacterial vaccines in question of the immunising substances which are desired. Again, quantitative estimations of the bactericidal powers of the blood of normal persons and of persons who have been inoculated with bacterial vaccines may quite well furnish important indications, in the first case as to the expediency of inoculation, and in the latter case as to the successful issue, or otherwise, of the inoculation. Lastly, by means of quantitative estimations of bactericidal power many theoretically important questions may be resolved. Among these may be mentioned the question as to the co-existence and inter-relation between the agglutinating and bactericidal powers of the blood. Without in any way undervaluing the important results already obtained by the initiating work of Buchner, it will be manifest that the investigation of most of these questions has hardly as yet been entered upon. It has been retarded by the fact that the technical methods which have been hitherto employed have necessitated the employment of relatively considerable quantities of blood, and have, in the case of agglutinating bloods, been associated with a serious source of fallacy, arising from the fact that the bacteria, which would normally be separately disposed, are under the influence of such bloods agglutinated together, with the result that the individual colonies which develop on the nutrient medium may be the outcome, not of a single surviving bacillus, but of a whole group of surviving bacilli. By means of the technique described below the sources of difficulty and error, which have been referred to above, can be effectually and, it seems to me, easily disposed of. The method is also a comparatively rapid one, it being possible, after practice has been acquired, to carry out about four quantitative determinations in the hour.

The principle of the method.—With a view of determining in a quantitative manner the bactericidal power of the blood measured volumes of serum and of graduated dilutions of serum are introduced into a series of "capillary cultivation tubes," along with a series of equal volumes of a gelatin culture containing an appropriate number of bacteria. Mixture of the contents of the serum and culture is then effected in the capillary tube. It will be noticed that by this arrangement the serum comes in contact with the bacteria only after these have been suspended in a fluid which is sufficiently viscid to make it impossible for them to come together into groups. After the gelatin has solidified the tubes are incubated for a period of two or more days. The number of colonies of the specific organism which develop is then elicited by counting under a microscope, the results of the enumeration being in each case compared with the results of the enumeration of the colonies in a series of control tubes filled with an equal volume of the gelatin culture duly diluted with an indifferent diluting fluid.

It will be convenient to begin the description of procedure by considering how the desired dilutions of the blood are made and the desired quantities of bacterial culture and serum are measured out. For these purposes it is convenient to make, as can readily be done by the following method, an accurately graduated capillary pipette.

Method adopted for dividing an ordinary capillary glass tube so as to make a graduated capillary pipette.—A piece of ordinary glass tubing of about a quarter of an inch (roughly 0·6 centimetre) in diameter is drawn out in the middle into a capillary tube of an approximate diameter of from $\frac{1}{60}$th to $\frac{1}{100}$th of an inch (from 0·4 to 0·25 millimetre). Before the glass has quite cooled the capillary end of the tube is bent round so as to make a right angle with the wider portion of the tube. *This done a stout glass capillary pipette, such as* the five cubic millimetre pipette, which is supplied with Gowers's hæmocytometer, is taken and filled in up to the calibration mark with a solution of eosin or other coloured fluid. The extremity of the ungraduated thin-walled capillary tube which is to be calibrated is now broken off and the tip of the stout glass capillary pipette is brought into apposition *with the broken end, this last* being during the operation held vertically upwards. By gentle blowing the measured volume of coloured fluid is now transferred to the ungraduated thin-walled capillary tube. The transference of the coloured fluid in an unbroken column can be effected without difficulty provided that the end of the thin-walled capillary tube has been broken off in an accurately transverse direction, so as to make it impossible for bubbles of air to be sucked into the orifice.

When the measured volume has been transferred without loss and in unbroken column into the capillary tube, the point of this latter is held downwards in such a manner as to allow the fluid to flow back to the point. A mark with a coloured wax pencil is then placed on the capillary stem to indicate the upper limit now attained by the coloured fluid. After the first division has been thus placed upon the tube the further calibration is undertaken in the following way. The point of the tube is again raised in such a manner as to allow the column of fluid to run back from the point until the distal end of the column of fluid corresponds with the division mark which has been placed on the tube. The point where the second division is to be placed on the tube is now manifestly indicated by the proximal end of the column of coloured fluid. Two divisions having been placed on the tube with a view to obviate, so far as possible, a progressive loss of fluid by adhesion to the walls of the tube, sufficient additional coloured fluid is introduced to fill the tube up to the second division. This done, the point of the tube is again raised and the fluid is allowed to flow back from the point until its distal limit is in apposition with the first division. The proximal end of the column of fluid will now indicate the place where the third division ought to fall. Proceeding in the same way—the next time filling in the tube up to the third division with coloured fluid—the fourth division mark can be placed on the stem of the capillary tube. A fifth and subsequent divisions if desired can be obtained in a similar manner. For the purposes of the method which is to be described below it will, when operating with an original volume of five cubic millimetres, be convenient to place only three marks on the tube in the manner indicated and then by a subsequent operation to subdivide each of these divisions into two equal subdivisions.

The process of subdivision in question is very simply achieved by the following system of trial and error. The first step is to guess the point on the tube where the first subdivision mark ought to be placed. This point may conveniently be indicated by a light pencil mark. This done, the coloured fluid is filled in up to this tentative subdivision mark. By tilting the tube the column of fluid is now allowed to run down from the point until its proximal end just touches the first of the original (five cubic millimetre) division marks. If it is now found that the distal end of the column corresponds accurately with the tentative subdivision mark this mark will manifestly have been placed exactly at the proper point. If, on the other hand, the distal end of the column of coloured fluid now overlaps or falls short of the tentative subdivision mark, a second light mark is to be placed on the tube to indicate the point upon which that distal end falls. The true point of bisection will now fall on a point of the stem midway between these two light marks. Having by the above procedure found the point corresponding to half the volume originally taken—in other words, to 2·5 cubic millimetres—the points corresponding with one and a half and two and a half volumes respectively are easily found by a procedure exactly identical with that described in placing the original, five cubic millimetre, division marks upon the capillary stem.

It is to be noted that it is not essential that the tubes should be graduated in terms of 2·5 cubic millimetres, or indeed of any definitely known measure; it will suffice for almost all purposes if the capillary stem is divided into equal arbitrary divisions by the method described in the paragraph last but one above. At the same time the calibration in terms of 2·5 cubic millimetres is convenient as giving definite indications of the actual quantities of bacterial culture and serum actually employed.

Method for obtaining the fresh serum required for the estimation.—The next point to consider is the method of obtaining blood serum for examination. Blood may be conveniently obtained from a prick in the finger and may be filled into blood capsules of the pattern elsewhere figured by me.[1] The blood capsule is, in accordance with a suggestion received from Major W. B. Leishman, R.A.M.C., introduced into a small hand centrifugal machine as soon as the blood has clotted. A clear serum is thus readily obtained within a few minutes after drawing off the blood.

Preparation of the bacterial culture employed in measuring the bactericidal power of the blood.—It will suffice under this heading to give indications as to how the bacterial culture is prepared in the case of the bacillus typhosus. The simplest method of operating is here to make a superficial stab into a gelatin tube (inoculating for this purpose from a broth cultivation) and to incubate this for from 12 to 18 hours at a temperature of about 22° C. If after this time the very first indications of growth can, on careful examination, be made out the culture may, after duly melting and mixing, be employed for the estimation of bactericidal power.

Failing a young gelatin culture such as is just described a suitable culture can be obtained by placing 2·5 cubic millimetres of a tenfold diluted young broth cultivation of the typhoid bacillus into a tube of melted gelatin. Similarly, if only an older stab cultivation of the typhoid bacillus is available, this may be diluted 10 or more times with gelatin. In this last case the amount of dilution necessary to give the required number of colonies in the culture tube will readily after a little practice be learned. Until this experience shall have been gained it will be safer to employ only quite young gelatin cultures. It is convenient to employ for the estimation of bactericidal power a culture containing not less than 50, and not more than 200, colonies in 2·5 cubic millimetres of gelatin.

Method of making the blood dilutions.—The indications given under this heading will again relate only to the case where the bactericidal effect upon typhoid bacillus is to be elicited. In connexion with such determinations it will be convenient to employ, in addition to undiluted blood, dilutions of five-, ten-, twenty-, and forty-fold. Dilutions of this order when mixed with equal volumes of gelatin may be expected to show bactericidal effects. Higher dilutions will occasionally be required. The dilutions are made by means of the capillary pipette, the motive force required being obtained by the compression or relaxation of a rubber teat fitted on to the broad end of the pipette. The means for making the five fold dilutions are provided by the division marks which have been placed on the stem of the pipette. The higher dilutions can be made from these primary ones. The procedure for measuring out equal volumes of typhoid gelatin and serum or serum dilution, and for introducing these into the capillary cultivation tubes, and for affecting the necessary mixture must next engage our attention.

Description of capillary cultivation tubes.—The capillary tubes which are illustrated in Figs. 1 and 2 are easily made in pairs by taking a piece of glass tubing of about three-sixteenths of an inch in diameter and drawing this out in a flame into a capillary stem of from one-sixtieth to one-hundredth of an inch in diameter. Before the glass cools the wider ends of the original piece of tubing are bent round upon the capillary stem in such a manner as to form a right angle with it. Finally, the capillary stem is burnt through in the middle, a slight pull being, during this process, exerted upon the ends of the tube in order to obtain

---

In every case young sub-cultures of a culture of a bacillus typhosus which had been recently isolated from a fatal case of typhoid fever were employed.

* The bloods employed were drawn off from healthy young men. In all but two instances these were Surgeons on Probation at Netley whose ages ranged between 21 and 28 years.

† The dilutions indicated by the figures represent the proportion borne by the whole contents of the cultivation tube to the contained serum.

‡ The serum in question was obtained by mixing together equal volumes of the serum of 10 Surgeons on Probation.

test-tube into another. *Secondly*, the capillary pipette must be carefully cleaned and warmed by washing it out each time in boiling sterile water. *Thirdly*, the gelatin culture must be kept well above its melting-point from start to finish. The cultivation tubes also should be kept on a warm shelf, both before they are filled in, and afterwards, during the interval between filling in and mixture. *Fourthly*, the mixture of the serum, or serum dilution, with the gelatin culture must be efficiently carried out. If this has not been done isolated colonies may, even in the case of tubes containing a highly bactericidal serum, make their appearance at one portion of the tube while the remainder of the tube is found quite sterile. Another point in connexion with the operation of mixing which has to be borne in mind relates to the shape of the cultivation tubes. In making these care must be taken to allow the glass to cool sufficiently to prevent it kinking at the elbow when it is bent round. Kinking of the tube at this point frequently entails the breaking of the column during the operation of mixing. *Lastly*, attention may be drawn to the fallacies which may be introduced into the observations by the use of an inappropriate diluting fluid. In the case of the bacillus typhosus normal salt solution is a very unsuitable diluting fluid. Where it is employed the number of colonies in the higher dilutions of the serum will uniformly be found less than in some of the lower dilutions. In other words, the suspension of the bactericidal powers of the serum obtained by dilution is, where normal salt solution is used as a diluting fluid, over-compensated for by the bactericidal powers of this last fluid. On the other hand, ordinary broth or, even better, saltless peptone broth, constitutes a very satisfactory diluting fluid, the number of colonies being in such a case always more numerous in the higher than in the lower dilutions of serum.

Preliminary account of some of the results obtained.—Having described the most important points of the procedure adopted, it may be well, in conclusion, briefly to glance at some of the results which have been obtained by the application of the above method. It need hardly be said that these are here dealt with only in a preliminary way, for it will be manifest that the problems which are opened up would require the unremitting labour of months, if not of years, for their effective solution. It will be convenient to begin with the bactericidal effects exerted by normal human blood upon the bacillus typhosus. The results of close upon 50 examinations of normal bloods (all instituted with young subcultures of a typhoid bacillus recently isolated from a fatal case of typhoid fever) show somewhat remarkable results. The bactericidal effect was in all cases found complete in a two-fold dilution. In 22 out of the 28 blood examinations separately tabulated above a complete bactericidal effect was obtained also in a 10-fold dilution. In 50 per cent. of the bloods examined the complete effect was obtained also in a dilution of 20-fold. In 15 per cent. it was again complete in a 40 fold dilution. Only in one case was the bactericidal effect complete in a dilution higher than 40. A conspicuous feature in the results is the very considerable individual variation in bactericidal power. It must be carefully understood with regard to these results that they apply only to the particular culture which was used. In a subsequent paper the question will be considered as to whether a greater bactericidal effect is exerted on cultures which have been attenuated by cultivation in artificial media than on cultures the virulence of which has been exalted by a series of passages through animals. Further, it is to be noted that the data which are given above apply in each case to the effect of sera which have been brought into application within two or three hours after the blood has been drawn off from the body. When sera are kept for a day, and even more so when they are kept for 48 hours, a very considerable decline in bactericidal power makes itself manifest. The data concerning this will also be given in a subsequent paper. Suffice it for the present that the results which have been obtained confirm in a general way those of Buchner. The same holds true with regard to the effect which is exerted on the bactericidal power by temperatures of from 56° to 60° C.

The modifications in the bactericidal power of human blood produced by additions to that blood *in vitro* of specific anti-typhoid sera may next be considered. Up to the present two different anti-typhoid sera have been studied from this point of view. Both of these were highly agglutinating sera placed on the market for therapeutic use. The effect produced by both these anti-typhoid sera were to a large extent similar. In every case even quite small additions of these sera to normal human blood brought about a complete, or all but complete, abolition of the normal bactericidal power of the blood, colonies of the typhoid bacillus making their appearance in large numbers even in mixtures containing one part in four of normal blood. Up to the present no increase of bactericidal power has been ascertained to result from the addition to a normal blood of the "therapeutic sera" in question. The importance of the issues thus opened up is immediately evident, for it is not clear that benefit would be derived from the therapeutic administration of a dose of serum which produces effects like these. It is conceivable that experiments of the kind now in question might throw an important light on the utility or otherwise of various other therapeutic sera, *in particular of certain anti-streptococcus and anti-plague sera.*

The question of the alterations in the bactericidal power of the blood which are associated on the one hand with attacks of typhoid fever and with convalescence from this disease, and on the other hand with inoculation with dead cultures of the bacillus typhosus, must be postponed for discussion in a future communication. With regard to the first of these questions it will here suffice to say that it seems possible, from the data which are already to hand, that indications which may be of use in prognosis may be deducible from observations on the variations in bactericidal power during the course of a typhoid fever. In connexion with the second question it will suffice to put on record that after an interval (during which it is possible that the bactericidal power is reduced) a definite increase in the bactericidal power of the blood comes under observation in guinea-pigs which have been inoculated with sterilised cultures of the bacillus typhosus. The data, which have up to the present accumulated in connexion with the effect of inoculation on the bactericidal powers of the blood in man, are not as yet sufficiently numerous to allow of a definite statement being formulated. There appear, however, to be indications that the course of events in the case of man will show a general correspondence with that which comes under observation in animals. In conclusion, it may be recorded that a large series of comparative quantitative estimations of the agglutinating and the bactericidal powers of the blood have shown (as was surmised by many observers, of whom the present writer was not one) that there is no *direct* association between these properties of the blood. I give a table which sets forth certain of the data obtained in connexion with the bactericidal power of normal human blood

Netley.

FUNGUS DISEASE OF THE EAR.

BY W. K. HATCH, M.B., C.M. ABERD., F.R.C.S. ENG.,
LIEUTENANT-COLONEL, I.M.S., PROFESSOR OF SURGERY, GRANT MEDICAL COLLEGE, BOMBAY;
AND
R. ROW, B.Sc., M.D. LOND.

IN order to show the frequency with which fungus disease of the ear is met with in Bombay during the rainy season I (W. K. H.) have collected all the cases treated at the Jamsetjee Jeejeebhoy Hospital during the month of October, 1899. I have verified diagnosis by microscopical examination and in several instances Dr. Row has kindly made a culture on agar-agar. Medical practitioners in Bombay often speak of the liability to disease of the external ear in this climate and they generally diagnose the conditions as furunculosis. I am convinced, however, that in most cases the disease is really aspergillosis and the small pustules seen in the canal are merely the result of a growth of a fungus. Von Roosa in his able work has tabulated several varieties and he states that in his opinion the fungus is the cause of the eczematous condition of the canal and not secondary to it. I quite agree with this opinion; moreover, it will be seen from the tabulated cases that in only one was there any pre-existing disease of the ear; this patient had a perforation and discharge some months before which had been treated and stopped by means of nitrate of silver. The ear remained well until the appearance of a fungus; there was therefore no discharge seen before the symptoms were experienced. Formerly there had been several recurrences of discharge with inflammatory symptoms from the affected ear and on none of these occasions was any fungus found, so that I may say that the fungus in all the cases was really primary. There appears to be a considerable difference in the symptoms due to fungus, varying from slight to considerable deafness and attended by pain which is occasionally severe. There is also a good deal of discomfort, generally described, in fact I may say almost universally, by native patients as "heaviness" and sometimes also "stuffiness," but this symptom varies, I think, according as to whether the canal is blocked up by epithelium and fungus or whether the growth is merely a coating to the canal of slight thickness. In most cases the membrana tympani is obscured from view by the growth, or red patches may be seen on it here and there. In a very few instances I have observed small patches of growth on the tympanum only, without any signs of inflammation. Roughly speaking, cases may be divided clinically into dry and moist; in the latter class the symptoms of eczema are present to a greater or less extent and there is therefore a watery or slightly purulent discharge from the ear, and slight pain and deafness with a feeling of heaviness are usually complained of. In the majority of cases the aspergillus niger is found. There is a quantity of moist-looking epithelium on which black particles are plainly visible, having an appearance of grains of gunpowder. If the particles are plentiful there is more black than white visible, but if there are only a few it may not be easy to distinguish them readily. After syringing and the removal of the mass the walls of the canal are seen to be red and denuded of epithelium and often irregular, with small furuncles and swellings, and the membrana tympani may be bright red in colour or dull and sodden in appearance. Often the aspergillus flavus can be seen growing on the surface of small superficial pustules and if in any quantity the small balls of sporangia are plainly visible. The growth of penicillium glaucum gives a fluffy appearance to the surface.

In the "dry" variety the symptoms of pain, uneasiness, and deafness are also complained of, but there is no discharge, and the canal on examination may be found either to be stuffed full of epithelial *débris* with yellow, black, or brownish-looking particles sprinkled on the surface, or the walls of the canal are coated with a crust, usually of a darkish colour, on which the fungus is seen growing. The appearance is not unlike that of rhinitis when dry crusts coat the surface of the mucous membrane; the tympanum is therefore visible but the surface is generally partially coated with a similar fungus to that on the canal. Sometimes white patches on the tympanum also are met with and they are difficult to remove. After syringing the walls of the canal appear red but dry and the membrana tympani is not so often inflamed as in the moist variety. Diagnosis is readily made after a few observations and confirmed by microscopical examination; sometimes the amount of spores is largely in excess of the mycelium.

The treatment which I have adopted in both varieties is the same and it consists in syringing very thoroughly and using iodoform and boric acid in equal parts. The canal may be swabbed out with camphorated salol, but the drugs used are not of themselves so important as frequent cleansing. It is not necessary to say more than this—that cleanliness and dryness are most efficacious.

Notes on some fungi recovered from the cerumen of the ear from the private notebook of Dr. Row.—Out of the 10 specimens which were kindly collected and sent to me for examination by Lieutenant Colonel Hatch, I.M.S., only one gave a negative result. From the rest a variety of fungi

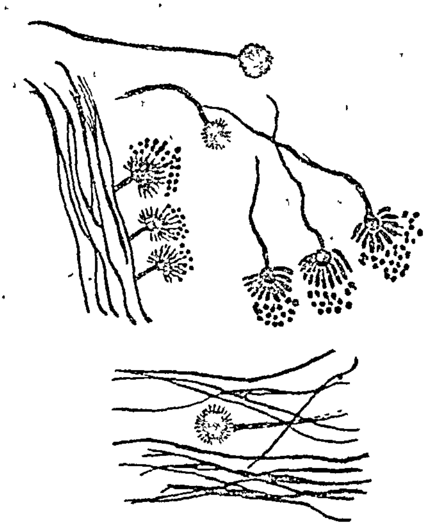
SUMMARY OF CASES OF FUNGUS DISEASE OF THE EAR TREATED IN THE JAMSETJEE JEEJEEBHOY HOSPITAL DURING OCTOBER, 1899.

No. of case.	Caste.	Variety of fungus.	Symptoms.	Appearances.
1	Hindoo.	Aspergillus flavus.	Four days' duration; slight pain and deafness.	The canal was not blocked; no discharge; yellow growth on the surface of the tympanum.
2	Mahomedan.	Aspergillus niger.	Deafness; severe pain in the parotid region of two years' duration.	At the bottom of the canal was a black mass with yellow spots on it. After removal the tympanum was red and angry-looking; the canal was sodden.
3	Hindoo.	Aspergillus niger.	A pricking sensation in the left ear and humming noises; pain in front of the tragus of three days' duration.	Blackish spots on the canal and on the membrana tympani; the spores were small and of a brownish colour.
4	Hindoo.	Aspergillus niger.	Pain and slight deafness of eight days' duration.	The membrana tympani was surrounded by yellowish-brown material and white towards the centre, due to a mixture of epithelium and black fungus.
5	Mahomedan.	Aspergillus flavus.	A pricking pain in the left ear of four days' duration.	The canal was very dry-looking. On the membrana tympani was a white patch with a yellow growth on it, and there was a similar appearance on the wall of the canal. Yellow fungus was found under the microscope.
6	Hindoo.	Aspergillus niger.	Pain in both ears for six days and also an itching sensation.	Both canals were choked with sodden epithelium. On these were black patches. Under the microscope large stalks of aspergillus niger and many spores were seen.
7	Mussulman.	Aspergillus flavus.	Pain, at first slight, in the left ear, but it gradually increased and a watery discharge appeared.	There was a watery discharge, the wall of the canal was eczematous. White spots were seen on the membrana tympani; a fine mycelium and yellow sporangia were seen.
8	Parsee.	Aspergilli flavus and niger.	Itching sensation in the left ear, with headache, tinnitus, and watery discharge. Similar symptoms in the right ear but not so marked.	The left canal had a dry appearance and on the anterior wall there was a dry whitish patch, while the *posterior* wall appeared dry and black. The right canal looked much the same. A mixture of both yellow and black fungus was found in both ears, the black variety predominating in the right ear and the yellow in the left.
9	Eurasian.	Aspergillus niger.	For two or three days the patient had suffered from a pricking sensation in the left ear, headache, noises, and restlessness. There were also a good deal of pain and deafness (of old standing).	Some thick pus and darkish fungus-like masses were seen in the left ear. On removal the membrana tympani was found to be inflamed and was perforated in the centre. This was an old perforation for which I had a few weeks before treated the patient. The fungus had a rusty brown colour under the microscope.
10	Mussulman.	Aspergillus niger.	For 10 days there had been pain and throbbing in the left ear, but no discharge.	The canal had a dry appearance. There were numerous spores of a dark colour, but no mycelium was found.
11	Hindoo.	Aspergillus flavus.	Throbbing in the ear of one day's duration with heaviness. There was no discharge, but there had been a little a few days previously.	The canal was lined by a coating of a yellowish colour, with white patches here and there. Yellow fungus was found.
12	Hindoo.	Aspergillus niger.	For three days the patient had had heaviness, deafness, and some pain in the left ear.	The canal was blocked with epithelium and dark masses which proved to be aspergillus *niger*.
13	Mussulman.	Aspergillus flavus.	For the last 12 days the patient had had slight pain, heaviness, and deafness of the right ear.	The canal was dry, with yellow spots on white patches. Yellow fungus was found.
14	Hindoo.	Aspergilli niger and flavus.	Slight pain and deafness of five days' duration.	The canal looked dry. There were a few pustules on the wall and black and white patches on the canal wall. Aspergillus niger was found and a few yellow sporangia were seen.
15	Mussulman.	Aspergillus niger.	Pain in the left ear of five days' duration and fulness.	The canal was dry. There were black spots on the walls. Aspergillus niger was found. There were small and very large stalks.
16	Mussulman.	Aspergillus flavus.	The patient complained of heaviness of the right ear of six days' duration. There was no pain.	The canal contained cerumen coated with a fluffy growth. Aspergillus flavus was found and large stalks and sporangia were seen.
17	Eurasian.	Aspergillus niger.	For six weeks the patient had had *itching* in the right ear and lately slight discharge. There was no pain and the hearing was not impaired.	The canal was inflamed and elsewhere covered with dry-looking epithelium. Plenty of mycelium and brownish spores were found.
18	Parsee.	Aspergillus albus.	Increasing deafness of three days' duration and a heavy sensation in both ears.	The canal looked eczematous. There was a quantity of white epithelium near the tympanum, the membrane being obscured. Fine mycelium was found, but there were no spores. Culture by Dr. Row showed aspergillus albus.
19	Jew.	Aspergillus albus.	Much pain in the left ear (more at night) and deafness.	The left canal was dry. White pustules were seen on the walls and also on the membra [illegible] Aspergillus [illegible] was found.
20	Mussulman.	Aspergillus niger.	Itching followed by pain of seven days' duration.	The canals were [illegible] Black spores and thick [illegible] in [illegible]
21	Mussulman.	Aspergillus niger.	Pain in the left ear with subsequent watery reddish discharge of three days' duration; no deafness.	The surface of [illegible] hes on the floor. Th [illegible]
22	Parsee.	Aspergillus niger.	For 15 days there had been pains and deafness in the right ear and three days previously a serous discharge was noticed.	

were isolated of which the most conspicuous were aspergilli of different species. From two specimens penicillium glaucum was isolated.

Method.—Of all the nutrient media used for isolation the one that answered best was maltose agar 2 per cent. Glucose agar answered next best. Ordinary peptone broth gave a fair growth of the mycelium and in depths the individuals formed flakes which on examination were found to be destitute of conidia. It is therefore interesting to see that under these conditions the increase in growth may simply be the vegetative increment of the mycelium. A great number and variety of staphylococci and streptococci were always found in the material used for inoculation and consequently in the original swabs. It was only by picking out the fungi of the higher order that pure growths were obtained and used for detailed study and examination The various specimens which were thus isolated appeared in the early stages of their growth so very similar, both in their naked-eye appearances as well as in their broad microscopical characters, that it was extremely difficult to relegate them to their proper suborder. Thus in 24 hours, just as is usual with all moulds, the individual colonies appeared as small specks, with firm, feathery radiations, the whole colony appearing perfectly circular. They were slightly white, and being translucent and thick no colour characteristics were detectable. At a later stage of their growth, however, identification was rendered easy by the following characters: (1) by the colour assumed by the sporangia *en masse*, this being more pronounced at the centre of the colony than at the periphery; (2) by the comparative size of the sporangia and their shape and minute details relative to the arrangement of the radiating sterigmata bearing the spores; and (3) by the temperature at which the various members grew best.

1. Thus aspergillus niger, aspergillus flavescens, aspergillus viridescens, aspergillus fumigatus, aspergillus albus, and aspergillus glaucus showed their various characters by the colour of the growth *en masse* That all these belonged to the aspergillus race was proved by the microscope which brought out all the characters easily. The character of the conidia requires scarcely any remarks as there was absolutely nothing new which could be observed, except in one case where both in the specimen as well as in the culture separate conidia were found of a nature which, by the pseudo-radiate arrangement of the sterigmata, roused some suspicion as to the mould being related to actinomyces. But subsequent culturing and staining by the Gram-Weigert method removed all doubts as to the identity of the specimen, which ultimately turned out to be aspergillus flavescens. The only points which may be mentioned here are: (1) the comparative size of the conidia in various specimens; and (2) the relation in size of the sterigmata to the conidiophore as seen in the various specimens. Thus of all the conidia those of aspergillus niger were larger than those of any other. The large size is partly due to the excess of sporulation, the spores in mature specimens growing to such an extent as to mask the minute structure of the conidia, which then appeared as irregular spheres. The sporangia in aspergillus glaucus were found to be the smallest and in some specimens the structure was clearly defined, the whole appearing perfectly symmetrical with the fine sterigmata radiating in such a way as to give the specimen an appearance not unlike a sunflower. The arrangement of sterigmata in these two specimens was, as seen from fresh as well as stained specimens, all round the clavate, flask-shaped or even spherical end of the conidiophore, the individual sterigmata radiating very symmetrically and giving rise to the appearances above indicated. The conidia in aspergillus flavescens and aspergillus viridescens, however, showed that the sterigmata in mature specimens were arranged round only a part of the circumference of the conidiophore, so that the whole fructification appeared like a half or three-quarter sphere when examined microscopically (see figure). The actual diameter of some of the conidia is as follows: aspergillus glaucus, 27μ; aspergillus viridescens, 72μ; aspergillus fumigatus, 31·5μ; and aspergillus niger, 108μ.



Aspergillus viridescens (3 B) Microscopic appearance, various stages of growth.

2. Without entering into details on the relation in size of the sterigmata to the conidiophore I may cite the instance of only one or two specimens where this was conspicuously noticed. Thus in aspergillus glaucus the central core of the conidium—that portion contributed by the conidiophore—is only 13 5μ, while that of the radiating spoke of the sterigmata is just half of this, while in aspergillus viridescens the proportion of the central to the peripheral zone is as 45μ : 13 5μ.

3 The most favourable temperature for the growth of aspergillus niger was found to be from 25° C. to 28° C., while that for all the rest was from 35° C. to 38° C

The following is the tabulation of the various fungi recovered from the specimens of cerumen which were collected for examination.

Nature of fungus.	Specimens of cerumen from which they were recovered.
Aspergillus niger on maltose agar (four days)	Specimen 1.
Ditto, microscopically.	
Aspergillus viridescens, four days on maltose agar	Specimens 2, 3, and 7.
Microscopically, in various stages of growth.	
Aspergillus fumigatus lighter.	Specimens 2 and 3
" " darker	
Aspergillus albus.	Specimens 1 & 10A.
Aspergillus glaucus, four days.	Specimens 1 and 2.
Microscopically	
Penicillium with oidio-spores, four days. Maltose agar	Specimen 10.
Microscopically.	
Aspergillus flavescens, very vigorous on agar (three days)	Specimen 6
Penicillium (greyish coloured).	Specimen 1
Pseudo-radiate arrangement of sterigmata in a mass of mycelium.	Specimen 3.

Since writing the above I (W. K. H) have had an opportunity of seeing the effect of administering subcutaneously some of the fungi above named to rabbits and monkeys. The lesions in these cases were invariably localised abscesses at the seat of inoculation, containing pultaceous, almost doughy pus, containing the mycelium as well as conidia The abscesses, as a rule, were well encapsuled, so as to admit of an easy dissection In one case where only the mycelium was inoculated the abscess contained more fluid contents tinged with blood This eventually burst and the parts healed. The further study of mycosis is still in progress A table of cases treated during October, 1899, is appended.

[The paper was accompanied by an excellent series of coloured drawings illustrating all the various forms of fungi mentioned. We regret that the space at our disposal does not permit us to reproduce them.—ED. L.]

SOME NOTES ON CASES OF MOVEABLE KIDNEY,

WITH REMARKS ON THEM.[1]

BY HENRY DAVY, M.D., F.R.C.P LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

"MOVEABLE KIDNEY" is not a very common condition, for on looking through my note-books, in which I have kept short notes of every patient whom I have seen at my house for the past 20 years, I can only find 14 patients in whom this condition has been certainly diagnosed out of the several thousands of patients who have passed through my hands during that period, although I have notes of 25 cases which presented some difficulty at first in determining whether this condition was present or not. I propose to bring before you notes of the most interesting of these patients which illustrate the difficulties that are met with in making a diagnosis or which raise points that seem to me worthy of consideration. Hilbert distinguishes two grades of these cases. In the first only the inferior pole and not more than the lower half of the kidney can be felt. This he calls the palpable kidney. In the second grade he places those cases in which "the whole kidney can be felt and can be isolated with the fingers." This he calls "moveable kidney." I very much doubt whether it is possible to say with any certainty that the condition which Hilbert describes as palpable kidney is the cause of any symptoms. At any rate, in the following case, in which recurring attacks of pain were attributed to this cause by two well-known physicians, this diagnosis proved to be entirely incorrect.

CASE 1.—The patient was a stout woman who was seen by me in consultation in March, 1886. She was about 50 years of age, had had three children, and for about one and a half years previously to my seeing her she had been having frequently recurring attacks of pain. These attacks usually came on when she had walked some little distance, but they also came on at other times as, for instance, after walking downstairs. The pain would seize her in the right side just below the ribs and was often so severe that she had to have morphia injections. The pain did not pass into the back or down towards the bladder and was never accompanied by jaundice. There was no evidence of disease of any of the organs, but when the late Dr. Walter Moxon saw her he thought he could feel the end of the right kidney. She was seen by Sir George Johnson and Dr. Moxon, who both considered her condition to be caused by a "loose kidney," slight twisting of which caused the pain. Dr. Moxon in a letter to me said: "I think the drag of a shifted kidney would account for all the symptoms, especially if the twist on its hilus which the kidney undergoes interfered at all with its circulation." In 1890 I again saw the patient in consultation with Dr. J. Mortimer under whose care she then was. She was dying from albuminuria and the attacks of pain had continued up to this date more or less as before. It seemed then as if she might have a stone in the kidney which had caused disease of the organ. Subsequently we made a very careful post mortem examination. The kidneys were absolutely normal as to position and were well fixed and well surrounded by fat. The capsules of both were adherent and they showed the ordinary evidence of chronic Bright's disease No calculus was found and there was nothing to indicate the cause of the attacks of pain. We proceeded to look for "gall stones," which was my original diagnosis of the cause of the attacks of pain when I saw the patient in 1886, but the gall-bladder was normal and contained no gall stones. On removing the liver and examining it very carefully we found a small, round, smooth gall-stone a little larger than a pea occupying the hepatic duct. This readily moved upwards and downwards and was without doubt the cause of all the symptoms which had been attributed to the "loose kidney."

With regard to the second grade in which "the whole kidney can be felt and can be isolated with the fingers," I would for purposes of diagnosis divide these cases into two very distinct classes. In the first the kidney can be felt in outline and can be replaced in its usual site in the loin and again displaced and replaced at the will of the examiner. The diagnosis of these cases is easy and mistakes are only possible when the condition is not looked for. As an example of this type I give the following case.

CASE 2.—The patient, a bright, highly educated single woman, aged 23½ years, had enjoyed very good health up to Christmas, 1897 In January, 1898, she drove nine miles to a county ball and danced several dances as usual. In the middle of a vigorous dance she felt suddenly so faint and sick that she had to lie down on a sofa upstairs for more than an hour and she could not again dance that evening. For the next three days she felt very unwell, with nausea but no sickness, after which she felt quite well. She continued well until March 11th when she was at a tiring social function standing all day. She hurried upstairs to dress for dinner and in the middle of dressing was attacked with sudden faintness and nausea which continued more or less for two or three days. She again appeared quite well until the middle of April when she undertook a railway journey to Bath, and on the night after her arrival, after running upstairs to dress for dinner, she was again attacked in the same way and affected for about the same period of time as before. After this she began to complain of pain in one spot about the centre of the epigastric region, and she complained of pain in this region whenever she swallowed food. She saw several medical men, who at first thought that she had obscure ulceration about the œsophageal end of the stomach, and she was kept in bed and dieted, but without avail. Then she was thought to have "nerves" and was ordered away to various places in Gloucestershire, Scotland, &c , for change of scene. It was noticed that for some days after all these journeys she was worse, with faintness, nausea, and pain in the epigastric region; then she would get better until she tried to exert herself, when after walking she always got an attack of pain or faintness and nausea. This state of affairs continued until January, 1899, when she was sent to London and rapidly in succession saw two eminent physicians there several times. She was said by both to be suffering from "nerves" and was ordered more changes of scene. Finally she was ordered by one of these physicians to have Weir-Mitchell treatment and she came under my care in the Home Hospital for this purpose. I found her a bright, cheerful, well-nourished patient, who did not at all seem to be suffering from "nerves." The curious history of her attacks led me to examine her carefully for a displaced kidney. I found the right kidney easily displaced so that it slipped down to the level of the umbilicus and was freely moveable between that position and the loin. The patient tried a pad and belt but did not care to wear it, and finally she saw Mr. Frederick Treves who stitched the kidney in position. I saw her 12 months after the operation when she appeared quite well; she could walk and apparently do anything that she wished without pain and without any return of her previous symptoms. She then told me that she had bought a bicycle in 1894 but had ridden it very little, as after riding it she always suffered from pain in the abdomen of so severe a character that she had to lie flat on the floor until it passed off. On making careful inquiries lately as to constipation her mother wrote to me saying that she had suffered much from constipation before her illness. It was obstinate, and she used to correct it with aperients, but after a time these failed; then after many days nature relieved itself but with much difficulty. She had no attack of pain but was, of course, much exhausted.

In the second class of case the tumour when found cannot be replaced in the loin. In these cases it is often difficult to make an accurate diagnosis. You have here to distinguish between tumour of fæcal origin, malignant tumour of the bowels and peritoneum, and small solid moveable ovarian tumours, and I have notes of each and all of these conditions in which it was quite impossible at once to arrive at a definite diagnosis. Hydrosalpinx, enlarged gall-bladder, the "tight lace lobe" of the liver, and hydatid disease, are also mentioned in books as causing difficulties in diagnosis, but I have never met with cases of these conditions which presented the least difficulty. It is well to recognise that these cases cannot be definitely diagnosed at a single interview. They require to be watched; possibly to be treated with

---

[1] A paper read before the Devon and Exeter Medico-Chirurgical Society.

enemas or aperients *In other* cases it is necessary to have records kept of the temperature; while the general condition *and weight of the patient* should be noted and the condition of the tumour carefully examined If these requirements *are not attended to serious* mistakes will be made, as happened in the following case

CASE 3 —The patient a widow, aged 60 years, who had had two children was seen by me on August 15th 1889 She considered herself to be quite well until about four months previously Since then she had had much flatulence with a constant desire to defecate. The motions, which sometimes occurred four or five times a day, were small but of the usual consistence and were covered with mucus She had lost five or six pounds in weight in the previous three *months* and she complained of weakness as well as of indigestion and *occasional* pain in the stomach My notes say "The abdomen is distended with flatus and the coils of the intestine can be seen together with peristaltic movements in them Just below the ribs on the right side there is a tumour the size of a hen's egg This is so freely moveable that I think it is intestine and is so hard that I do not think it is fæcal The rectum is very freely dilated and I can detect no growth in it Her weight, 99 lb" I prescribed one minim of carbolic acid and quarter of a grain of extract of belladonna three times a day My notes of Sept 29th run thus "The patient has got on better and gained four pounds in weight (weight in some clothes 103 lb) The abdomen is much less distended and she has had no pain in the bowels The tumour is still in the same position but I think it is a moveable kidney, it appears reniform in shape with a depression in front which corresponds to hilus of kidney" Between that time and January, 1892 the patient paid me only seven visits She continued pretty well, varying up and down, sometimes losing two or three pounds in weight and sometimes picking these up again She continued her carbolic acid and belladonna pill twice daily and occasionally she took two or three teaspoonfuls of castor oil which invariably brought off a good deal of blood stained mucus as well as excreta The tumour continued the same and I never had any doubt during this time but that the tumour was a moveable kidney In January, 1892, she had an attack of influenza and became very weak She did not pick up but lost eight or nine pounds her weight going down to 93 lb She became dissatisfied with my opinion so I *sent her to* one of our leading London physicians giving him particulars of the weights, &c, which I had observed He took a very *different* view of her case and in a letter to me dated March 13th, 1892 he wrote as follows "There is no doubt about the case any longer She has a growth in the bowel and I think in the peritoneum also for I can feel lumps in several places and inasmuch as the bowel contents above a *stricture are almost never scybalous the lumps can only be* contracting muscle or growth The mass in the right side which seemed at first to you to be moveable kidney is, I suspect, also a mass of growth, for I can feel nothing of it *in the loin as one usually can in a moveable kidney* And if it be growth I suppose it would be a growth *in the hepatic* flexure or the omega lip of the sigmoid spread out, as is most commonly the case But I am not sure of this, because I can feel a polypoid growth in the rectum at the *end of the finger,* and that is very suggestive of a growth in the near neighbourhood *of which it is an outpost* I cannot *feel* the stricture itself" He prescribed an aperient pill with some mild *tonic which she took* She rapidly *got worse* and required daily visiting so I handed her over to my friend Mr J D Harris, who had attended her family in previous years *Shortly after complete obstruction supervened* and it was thought advisable, after consultation with Mr A J Cumming to perform lumbar colotomy Mr Harris performed colotomy in the ordinary way and he performed a most difficult operation extremely well, for he found *the colon completely* empty, and it is a *matter* of some difficulty to perform colotomy on an empty colon Within a week the patient died and at the post mortem examination we found (1) that the tumour which I have described was the right kidney which was freely moveable and which seemed in every way more or less normal, and (2) that there was a band of adhesion which seemed to be inflammatory in its origin just below the position in which this kidney usually lay This constricted the ascending colon just as it commenced to ascend at two or three inches from the cæcum and caused an obstruction The cæcum behind this obstruction was much distended being as large as a small stomach and the bowel behind this was distended with flatus as may be seen in ordinary cases of obstruction There was no growth of any kind in the bowel or anywhere in the abdominal cavity

This case is the only one of moveable kidney in which I have been able to make a post mortem examination and it is from many points of view very instructive It first of all shows the impossibility of diagnosing the cases which I have placed in my second class by merely taking into consideration the physical examination of the tumour and abdomen For here was a palpable tumour which appeared to one observer to have all the characters of a moveable kidney while to another it appeared *altogether different* It shows, too, that not always is anything of a moveable kidney felt in the loin, although there seemed no reason why this kidney could not be replaced in the loin as in the cases of the first class And further it shows how intestinal obstruction may be caused by bands of inflammatory material even when a moveable kidney is present, and I think this is a more likely cause than by the renal pressure to which it has been sometimes attributed Just below the place where the kidney usually lay was a band of inflammatory material causing a constriction and I think that it is not improbable that kidneys moving about freely in the abdominal cavity often give origin to similar bands of inflammation which interfere with the action of the bowels in various ways and possibly prevent these kidneys from being replaced in the loin In this connexion it is interesting to note that in Case 5, in which I saw the patient at intervals of a year, the kidney did not appear nearly so moveable at the second examination as it had always done previously

There are two *symptoms* associated with *dyspepsia* and various obscure abdominal pains which always make me examine for moveable kidney in a neurotic woman These are recurring attacks of faintness and recurring attacks of nausea or sickness for neither of which any very evident cause can be found Recurring attacks of faintness were a very prominent symptom in Case 2 and the same symptom will be observed in Case 4, while faintness and sickness constantly recurred in Case 5 and also in Case 10

CASE 4 —The patient a single woman, aged 25 years, had enjoyed very good health up to a year previously to my seeing her, when possibly she overstrained herself in riding 45 miles against the wind in one day on her bicycle There was also a history of a possible strain when she pulled a girl companion into a boat from which she had fallen She had also suffered from much constipation and straining at stool on several occasions, especially while taking a strong iron tonic shortly before her illness A note of the case taken at this time reads as follows "Illness commenced by her suddenly feeling faint in church and this has continued a symptom more or less ever since She then began to get *weak and generally* seedy with a dirty coated tongue and nasty taste in her mouth She lost appetite and complained of a good deal of pain across the lower part of the abdomen and in the back" She was treated for indigestion especially with intestinal antiseptics and the Salisbury diet and was brought to me by her medical attendant because she was no better and as she was getting nervous and apprehensive that something altogether wrong was going on inside I found all her organs healthy, but the right kidney was freely moveable It could be moved from the loin to the level of the umbilicus and could be easily replaced For the past two years the patient has worn a belt with a pad which seems to keep the kidney in good position and she has had practically no further inconvenience from her kidney and is now in good health

CASE 5 —The patient in this case was a married woman, aged 43 years, who had had no children She had never been robust and she used formerly to suffer from neuralgia of the head and teeth which ceased after her teeth were put thoroughly right Her menstrual periods were normal in every way Her bowels, as a rule, were very constipated For several years she had suffered every two or three weeks from attacks to be subsequently described which she thought had been caused by over fatigue cold and indigestible food The attacks commenced with pain which began on the right side near the spine and passed forward to the epigastric region in front After a time she seemed to have discomfort all over the abdomen and often got very faint She was troubled with flatulence and if this did not pass off it ended in sickness After these attacks the urine was highly coloured with a red sediment like brick dust The liver the heart and the lungs were normal In the right iliac region was a tumour which was smooth, of the size of an ordinary kidney, and reniform in shape. It was easily moved upwards toward the right lumbar region, but this gave some pain and it could not be moved into the normal position of the kidney. The patient could not remember to have had any strain but she had always suffered very much from constipation. She was once quite free from attacks for nine months, during which time she was taking Carlsbad salts every other morning. I saw her again one year after her former visit. The kidney was in the same condition but was not nearly so moveable She had not had any constipation and she had had no attacks of pain.

In considering the causes which predispose to, and which bring about, this condition I am not going to refer to the anatomy of the kidneys or to the supports by which they are usually kept in position. The anatomy and supports of the kidney are more or less the same in men as in women, and yet the condition of moveable kidney in men is so rare that personally I have never yet seen it. This is the more remarkable because if we consider the so-called immediate causes of dislocation—a blow, a fall, a twist of the spine, carrying a weight on the back when the body is bowed forward, violent coughing, or straining in vomiting or parturition—we shall recognise that with the exception of straining in parturition men are very much more exposed to these causes than are women. We have, then, to find something which is especially peculiar to women which will account for the fact that moveable kidney is so much more frequently found in them than in men. Many writers have considered that moveable kidney is most frequently associated with pregnancy and that most cases are recognised for the first time when the abdominal parietes are relaxed by parturition. My cases do not bear out this view at all, for of the 14 cases which I have collected five occurred in unmarried ladies who had never been pregnant and three in married women who had never had any children, while of the other cases in two each patient had had one child only, in one the patient had had two children, in one four children, in one five children, and in one 15 children. I do not think it is at all certain that pregnancy predisposes to moveable kidney. Nearly every week at the hospital, at the dispensary, or in my private practice I get cases of various displacements of the uterus associated with, or caused by, pregnancy or frequent parturition, but I have never found among these a case of moveable kidney due to this cause, although I have repeatedly examined for this condition in the cases of a very large number of these patients. Other authors have pointed out the influence of tight-lacing as a cause of the displacement and Hertz has shown that "in most cases the tight-lace line on the liver is on the same level as the upper pole of the kidney." But how common tight-lacing is, and how comparatively rare is the condition of moveable kidney. It is my belief that a large proportion of the anæmia in girls is due to tight-lacing, and for several years it was a custom of mine to measure the waists of all the anæmic girls who came before me at the Exeter Dispensary and the corsets they were wearing, and I have records of dozens of cases of anæmia in which waists which naturally measured 22, 23, and 24 inches were compressed into corsets measuring 19, 18, 17, and 16 inches. Yet I never met with a single case of moveable kidney amongst these anæmic girls attending the dispensary, though I have repeatedly seen their livers displaced by tight-lacing, and in one of my private patients the liver was so displaced from the same cause that it filled the abdomen to the level of the crest of the ilium.

Several of my cases have much impressed me with the part which chronic constipation and the straining which is often associated with it play in producing moveable kidney. Constipation, more or less marked, seems to be of such common occurrence amongst women that it may almost be reckoned amongst their sexual peculiarities. We may call to mind the dictum of a celebrated London lecturer who commenced his lecture on gynæcology as follows: "Woman, gentlemen, is a creature of periodicity. She micturates once a day; she defecates once a week; she menstruates once a month; and she parturates once a year." And although I am not prepared to say that this is an exact representation of the facts, yet it serves to remind us how much more common it is to meet with obstinate constipation in women than in men. I am inclined to think that the influence of obstinate constipation as one of the causes producing moveable kidney has not up to the present been sufficiently appreciated. Landau believes "the dragging influence of a colon distended with fæces to have some effect on the production of the displacement," but, as far as I have been able to ascertain, no one has discussed how far the straining at stool which so often accompanies habitual constipation may be a cause of the production of a moveable kidney. That it may be so sometimes is well illustrated by the following cases.

CASE 6.—A married woman, aged 48 years, with four grown-up children, frequently consulted me from 1894 onwards for headaches associated with very persistent and obstinate constipation, and I am certain that she then had no abnormality of the kidney. In January, 1899, she came to me and gave the following history. On going to the water-closet one morning she found herself very constipated, and whilst straining she felt a severe pain on the right side and also felt a lump just below the right ribs. The pain was so intense that she had some difficulty in getting back to her bedroom, where she remained for several hours on the bed, the pain gradually passing off. Since that time she had several times felt a "lump below the ribs." I saw her about a week after this attack. I found all the abdominal organs sound with the exception of the right kidney. This was easily felt just below the ribs in the nipple line. It could be moved downwards to the level of the umbilicus and could readily be replaced in its proper position in the right loin. The constipation has since been treated and the kidney has caused no more trouble.

CASE 7.—The patient was a woman, aged 34 years. She had been married for five years and had one child, who was two and a half years old and whom she had suckled for two years. She had not noticed anything the matter and was more or less well up to a month previous to my seeing her, when she had received a nervous shock through a lady opposite her house going "raving mad" and much disturbing her. Her bowels became very constipated, her tongue got furred, and she lost her appetite. 14 days before I saw her she was one morning, shortly after she had had an action of the bowels, suddenly attacked with great pain in the right hip inside. She was also complaining of "pain on the right hip inside" when she came to me. On examination of the abdomen I found that the right kidney was moveable, lying just above the crest of the right ilium, and that it was easily moved up again into the right loin.

It will be remembered that the patient in Case 5 had her bowels as a rule very constipated, that once for nine months she was free from the attacks of pain, &c., during which time she was taking Carlsbad salts every morning, and that after seeing me in 1897 she had no attacks of pain for one year, during which time she had prevented her bowels from being constipated. The patients in Case 1 and in Case 4 also gave histories of constipation and straining at stool shortly before their illnesses commenced. I do not think that this "straining at stool" can be by any means a rare exciting cause of moveable kidney when it can be directly traced in two out of 14 cases and was probably the cause in several others. The point is one of practical utility and I am sure that I have done great good in several of my cases by seeing that the patients attended carefully to the condition of their bowels and prevented any constipation and straining by the use of aperients.

It is, of course, a question whether the habitual constipation of women is not connected with the corsets which they wear, and whether these articles of dress do not therefore predispose to moveable kidney both by producing constipation and by exerting pressure on the upper pole of the kidney, but as far as my experience goes tight-lacing of itself is much more prone to produce displacement of the liver and uterus than of any other organ.

I would call attention also to the fact that in two of these cases the patients were inclined to put down their trouble to bicycling. The patient in Case 2 "had bought a bicycle in 1894, but had ridden it very little as, after riding it she always suffered pain in the abdomen of so severe a character that she had to lie flat on the floor until it passed off," and the patient in Case 4 enjoyed very good health up to a year before I saw her, when she possibly overstrained herself in riding 46 miles in one day against the wind on her bicycle. In both these cases, however, there were other causes which were more likely to have produced the displacement of the kidney. It would be worth observing whether moveable kidney is becoming more frequent since ladies have taken to bicyling, and whether bicycling can really be put down as one of the causes of its production. I can quite imagine that riding over a very uneven road might jolt a kidney out of position if it were already moveable, but I do not think that a normal kidney would be loosened by this form of exercise

When we come to consider the treatment of moveable kidney we are met with the fact that many patients who are the subjects of this condition get through life with very little inconvenience at all The displaced kidney seems very often to produce no symptoms as long as it remains quiet in one place Thus in Case 8 which is that of a single woman, aged 40 years who has been under my observation at frequent intervals for the past seven years, there are as a rule, few, if any symptoms so long as she leads a quiet life and keeps her bowels open At intervals she has to nurse and to lift an old mother, and this nursing is always attended by severe attacks of pain in the abdomen, and on several occasions after such nursing I have found on examination the position of the kidney to be shifted If, however, the kidney remains in one position the system seems to become accommodated to the displacement and few symptoms result I could quote several cases in which a moveable kidney has been under observation for years, causing very few symptoms but occasional indigestion, and requiring neither support nor treatment One of the first cases (Case 9) of consultation which I had in Exeter 20 years ago was with Mr A C Roper on a case of "floating kidney" The patient was never, and has never been, in robust health, and has always had indigestion, but she has gone through life as well as numerous other weakly women who have their kidneys normally placed

I think that all cases of moveable kidney suffer more or less at times from indigestion There seems to be a connexion between certain conditions of the kidney and stomachic disturbance

I have seen two cases which proved to be those of calculus in the kidney in which the patients had for a long time previously to the passage of the calculus only been thought to suffer from severe and intractable dyspepsia and from this condition only, and I see that Dr Clifford Allbutt, when enumerating the symptoms of calculus of the kidney, says "Another symptom which results from transference of nerve influence has reference to the stomach, nausea vomiting, and dyspepsia are very common not only at the times of actual colic but also during the periods of less acute suffering These symptoms are explained through the connexion of the pneumogastric with the renal plexus" It seems to be reasonable to suppose that the traction and twisting which a displaced kidney must make on the nerves of the renal plexus would produce indigestion in the same way as does the calculus in the kidney through the connexion of the pneumogastric with the renal plexus It will, I think, be found that the indigestion associated with moveable kidney is more benefited by aperients and by regulating the bowels than by any other treatment

In some cases moveable kidney seems to disappear without treatment, the kidney resuming its usual position This occurred in Case 10

CASE 10 —The patient, a married woman, aged 45 years, had had five children In 1889 twins were prematurely born and there were subinvolution and cervicitis of the uterus She was treated by Dr L Atthill in Dublin with much benefit At this time there was no suspicion of a "loose kidney" Some time in 1892 her husband (a medical friend of mine) was examining her abdomen to discover the cause of sudden attacks of faintness with sickly pain and vomiting from which she was suffering and he discovered an abdominal tumour The shape and smooth feeling of the kidney were very perceptible and its absence from the left loin was very noticeable, it being, as is unusual, the left kidney which was displaced The patient was seen by a surgeon who *entirely confirmed* the diagnosis A pad with a belt was devised, but the patient could not, or did not, wear it very long The symptoms gradually subsided and now nothing can be found in the abdomen

These, then are the most favourable cases of moveable kidney In other cases as I have mentioned in some of those which I have described, the symptoms seem to subside when the patient wears an abdominal belt with an inflatable pad over the region of the kidney in front which keeps the kidney from constantly shifting its position, but in some cases as in Case 2 this belt is of no avail—the symptoms continue and the patient's life is rendered very miserable especially when as in this case, a young person is cut off from dancing, tennis and all the pleasures which are most enjoyable at her age In such cases the operation for fixing the kidney should be recommended I am told by surgeons that it is a very easy and very satisfactory operation and my own very slight experience of it would entirely confirm this view

Exeter

THE OPEN-AIR TREATMENT OF PHTHISIS AN INTERESTING CASE.

BY J FLETCHER LITTLE, M B CANTAB, M R C P LOND,
PHYSICIAN TO OUT PATIENTS AT THE NORTH LONDON HOSPITAL FOR CONSUMPTION,
AND
F W FORBES ROSS, M D EDIN, D P H,
CLINICAL ASSISTANT AT THE NORTH LONDON HOSPITAL FOR CONSUMPTION

THE following case of pulmonary tuberculosis is published as an interesting example of the benefits to be derived from the open air method of treatment, accompanied by special feeding, in this country, as a contrast to one of residence in a warm climate unaccompanied by any special line of treatment, and also as an object lesson in the success that may be attained by appropriate treatment in the climate of this *country even when, as in this case, during residence abroad*, the disease had progressed and was rapidly nearing a fatal termination

A young man, aged 24 years, who was the subject of pulmonary tuberculosis on medical advice went to South Africa in November, 1897 At that time he was stated to be suffering from tuberculous infiltration of the apex of the left lung He resided for two years at Reddersberg in the Orange Free State where the climate is described as being fairly equable, and the place as hilly, sheltered, dry, and free from dust Reddersberg is on the main line to Bloemfontein and is consequently fairly well supplied with the necessaries of life During the patient's residence at that place he followed the light employment of a bookkeeper, spent a great deal of his time in the open air, and continued to carry out the lines of treatment which had been laid down for him by competent medical advisers at home and abroad His complaint at first tended to improve but he began gradually to lose ground till in April, 1900 he appeared to be so obviously going down hill that it was decided that he should return to this country and seek for further aid and, if it was possible, amelioration He accordingly presented himself in May at the out patient clinique of the North London Hospital for Consumption On examination the case presented the following noticeable points The patient's general appearance was that of a person suffering from a rapidly advancing wasting disease He was thin, pale, and emaciated His voice was husky and hoarse and only equal to a whisper He had an incessant cough with copious purulent sputum which on bacteriological examination showed crowds of tubercle bacilli by Gram's, Ziehl Nielsen's, and Honsell's stains His skin was dry, rough, harsh, and inelastic There were loss of appetite, pain after food, and frequent vomiting due to cough His height was 5 ft 9½ in and his weight was 8 st 9 lb His case was one of mixed infection On closer examination both lungs were found to be throughout in a condition of actively secreting bronchorrhœa, the apices of both lungs were dull and the left apex was the seat of a vomica below the sternal end of the clavicle Laryngeal examination showed pyriform swellings and slight ulceration with congestion of the whole larynx, all undoubtedly tuberculous His temperature ranged from 101° to 102 8° F daily His heart sounds were normal, though weak, The pulse was frequent, there were copious night-sweats and clubbing of the fingers, also slight anasarca of the feet His urine was free from albumin or sugar, but it was loaded with phosphates

His appearance being so obviously serious and as he needed immediate care and nursing, it was deemed advisable that whilst waiting for a vacant bed he should be sent into a general hospital as an in patient After residence in such an institution for a fortnight, during which time he made no favourable progress he was removed to his home by his friends, here he continued to reside during the space of five weeks, during which time he carried out as best he could the instructions which had been given to him for the application of the open-air methods. At the end of this period he had so far improved and was so much better, having gained five pounds in weight, that he appeared to be a more suitable case for treatment at Mount Vernon, Hampstead. He was therefore admitted into that institution on July 25th, 1900, when he weighed 9 st., and here he continued to reside and to enjoy the open-air treatment with appropriate remedies and diet under the care of Dr. B. O'Connor until Sept. 27th, when he left weighing 9 st. 12 lb.

The patient was now so much improved in health that when he presented himself for examination at the out-patient clinique in Fitzroy-square in October he was unrecognisable as the same patient. His appearance was that of a fairly nourished young adult. His voice was strong with the merest suspicion of huskiness, the laryngeal affection having markedly subsided under the care of Mr. R. Lake. His cough and night-sweats had disappeared and the bronchorrhœa had dried up, the only remaining signs being in the apices. The right apex had markedly cleared up, though the breath sounds were still harsh and the left apex showed fibroid thickening with the original vomica. There were very few bacilli in the sputum. His skin was now moist, oily, supple, and elastic, with some subcutaneous fat and a decided pinkness of hue. He expressed himself as never having felt better in his life, and his spirits and bearing conveyed that impression. At the present date he continues to attend the out-patient clinique and he carries out the principles of the open-air treatment at home in the country near London. His weight is now 10 st and he continues to improve in every particular.

This case is a good example of the prompt abatement and arrest of symptoms tending at one time to indicate a rapid progress towards a fatal termination. Although it is yet somewhat early to speak of "cure," yet from the progress of the case and its present condition there seem to be substantial grounds for much hope, as the patient appears to have now an excellent chance of recovery, which he certainly had not before the open-air treatment was adopted. The case is put on record as a sufficiently striking example, among many others, of the benefits of the open-air treatment of tuberculosis. At this time information as to the results of this method may be valuable and helpful to others who may desire assistance in deciding upon a line of procedure in suitable cases.

SOUTH AFRICAN HORSE-SICKNESS: ITS PATHOLOGY AND METHODS OF PROTECTIVE INOCULATION.[1]

BY ALEXANDER EDINGTON, M.B., C.M., F.R.S. EDIN.,
DIRECTOR OF THE COLONIAL BACTERIOLOGICAL INSTITUTE,
CAPE COLONY.

THIS disease, so far as is known, is peculiar to South Africa. While affecting the Transvaal and Rhodesia every year—beginning about the end of October and continuing until the following May or even later—it only affects the Cape Colony and Natal in an epizootic form in certain years, although sporadic cases occur annually in certain localities. It affects horses, asses, mules, and it has been asserted—although I have never seen such cases—that quaggas have also been killed by it. A disease which occurs to a limited extent among cattle, called by the natives "imapunga," and one which exists as a widespread plague among high-bred sheep and goats in the eastern province of Cape Colony, are each closely related in their pathology with this malady. The most dangerous areas infected by the disease are those which are relatively low-lying—independently of the absolute altitude of the district.

Period of infection.—It has been commonly observed that where animals during a season of sickness are not permitted to graze after sunset and before the sun has dried up the dew from the herbage they do not so commonly become affected as where such a routine is not carried out. Horses which are stabled during the night are, as a rule, safe, but during last year 60 per cent. of the stabled horses in Eshowe, Zululand, died from this sickness. Veterinary-Lieutenant Coley, A.V.D., who kindly made the observations for me, stated that these horses were mainly fed on Guinea or Ubaaba grass mixed with forage or Indian corn. This grass was usually cut in the evenings and made into bundles till next day. Those who took particular care to have the grass thoroughly dried in the sun before using it did not lose their horses, while those who neglected this precaution lost heavily. The disease is only directly contagious; for while inoculated horses have died in my stables among clean animals I have never found, during observations extending over seven years, a single case of infection from such a source. The annual mortality in Rhodesia and the low-lying parts of the Transvaal amounts to over 90 per cent. Animals which have recovered from the sickness are termed "salted," and are increased from six to ten times in market value. Animals which are "salted" are liable to subsequent attacks of fever which have no necessary relation to fresh infection. I have observed numerous cases of this description among the "salted" animals under my observation and during periods when the sickness was unknown.

Symptoms of the disease.—The disease occurs under two forms—the "dikkopziekte"[2] and the "dunpaardeziekte"[3]. In the former the head and neck swell up enormously, thus affording trustworthy indications of illness during life. In the latter form, as a rule, no symptoms appear until close to the period of death, when the animal becomes subject to very rapid breathing with heaving at the flanks. At the moment of death, in both forms, it is common to find a huge cloud of white foam ejected from the mouth and nose. This foam is produced from a free exudation of blood plasma into the air-passages. Owing to the fact that the animals suffering from the "dunpaardeziekte" show no symptoms until toward the end of the period of illness, it had come to be believed that the whole period of the disease was limited to a few hours' duration.

Post-mortem phenomena.—The pericardium is almost invariably filled with a yellow fluid which, while usually clear, is sometimes blood-stained. Solidified gelatinous exudate is frequently found in relation to the beginning of the aorta. The pleural cavity is frequently occupied by yellow fluid and the interlobular and sub-pleural tissues are also frequently distended by this material. The interlobular tissue is frequently so distended by exudation that the lung tissue proper is dissected up in all directions. The subcutaneous tissue, especially about the great vessels in the neck, is commonly found to be invaded by this exudation, while in the "dikkopziekte" the swelling of the head and neck is due to this effusion. The yellow fluid of the pericardium and the pleuræ is spontaneously coagulable in the presence of minute traces of blood. These represent the more characteristic pathological conditions obtaining in this disease, among which one characteristic is most noticeable by its absence—e.g., inflammatory phenomena. Pathological phenomena are, therefore, for the most part to be ascribed to the marvellous exudation of blood plasma which, while seen more or less throughout the serous and subcutaneous tissues, is best marked within the thoracic cavity. In my annual reports as Director of the Colonial Bacteriological Institute I have referred to the morbid anatomy in greater detail.

INOCULATION EXPERIMENTS.

For the purpose of conveying to healthy animals the infection from those already sick three materials have been made use of—viz., (1) the yellow fluid from the trachea of infected animals; (2) the yellow fluid from the pericardium of infected animals; and (3) the blood of infected animals. The use of the first two fluids has not always been successful in setting up the disease, but fresh virulent blood has invariably proved successful. The methods of use of the materials mentioned are: by subcutaneous injection; by the insertion of a seton, impregnated with the fluid, under the skin; and by drenching—e.g., giving a dose by the mouth. The sites selected are: directly into the lung tissue by hypodermic needle operating through the skin over an intercostal space; into the subcutaneous tissue of the neck; into the subcutaneous tissue of the flank; and intravenously. Any one of the channels selected is equally suitable, but the incubation period is somewhat shorter when the intravenous method is used. When the malady is induced by the inoculation of two or three cubic centimetres of the blood of an animal which has died from spontaneous disease, a mean period of from eight to nine days supervenes, after which the temperature begins to rise The elevation is gradual, with remissions during the night, but it attains to 106° F, as a rule before death, which usually occurs after four or five days of fever

---

[1] A paper communicated to the Royal Society for the author by Sir David Gill, F.R.S., on August 20th, 1900.

[2] Dikkopziekte, a Dutch word signifying "thick head sickness," is applied to the form in which the swollen head is the most obvious symptom.

[3] Dunpaardeziekte, "thin horse-sickness," applied to the form in which the head is little or not at all swollen.

After having transmitted the disease through a succession of animals I found it possible to preserve its virulence unimpaired through a long period of time I bleed the animals into bottles which hold 800 cubic centimetres of fluid These bottles are prepared by placing in them 50 cubic centimetres of a 10 per cent solution of neutral citrate of potash and plugging the necks with cotton wool Such bottles are sterilised in the autoclave previously to use After being filled with blood the influence of the citrate arrests coagulation and the corpuscular matter soon subsides leaving the more or less clear plasma above The latter is drawn off to half the original bulk and is replaced by a 50 per cent solution of glycerine and water, containing 0 25 per cent of pure carbolic acid Such a mixture preserves its virulence quite unimpaired for over two years One cubic centimetre of this material serves to induce the disease in its characteristic form, but if the dose is increased to three or five cubic centimetres the period of incubation is shortened and the post mortem phenomena are less characteristic

From the observations which I have made I have found that the subcutaneous injection of fresh or properly preserved horse sickness blood produces symptoms during life, and shows pathological changes after death which are not to be distinguished from those found in the spontaneously occurring cases of the lung form of the disease It is somewhat remarkable that the only cases in which I have succeeded in producing the "dikkop" form were those in which the virus which was used was somewhat septic When however, I have inoculated virulent preserved blood into partially protected animals I have in a number of cases although not in all, produced this form In three cases where the virus used has been sufficiently attenuated not to produce death but a longer febrile period than is found in the fatal cases, I have also seen the "dikkop" form produced

Citrated blood dried in a thick layer was rendered non virulent Where, however, such blood was rapidly dried on glass plates in very thin layers it was found when two grammes were dissolved in salt solution and injected into horses that it produced fever, but not in a virulent form The fever thus induced gave practically no protection against a dose of virulent blood at a subsequent date Mild attacks of horse sickness do not, however, give such protection as is required to resist virulent blood

Experiments made in regard to protective inoculation —The yellow fluid from the pericardium of an animal which had died from the disease was filtered through a Pasteur filter 100 cubic centimetres of the filtrate were injected subcutaneously into a horse 11 days later it was inoculated with three cubic centimetres of preserved blood injected subcutaneously The result, which culminated in death from ordinary horse-sickness, showed that no protective influence had been exerted by the filtered fluid

Calomel in doses of from 30 to 60 grains daily had the effect of retarding death and the blood of such animals drawn at periods later than that at which death usually occurs was distinctly weakened in virulence Such blood has on several occasions though not on all, induced attacks of the disease from which the animals not only recovered but acquired protection against virulent blood injected subsequently

Transference of the disease to other animals —The subcutaneous or intravenous inoculation of donkeys with fresh virulent blood is followed by fever The period of onset is irregular and uncertain, while the duration of the febrile period varies from one or two days to in my experience a week or more The amount of the virus used has some relation to the severity of the fever, but the special susceptibility of the animal is the principal factor in determining the degree and duration of the fever Two donkeys, equal in age were inoculated respectively with one cubic centimetre and 50 cubic centimetres of the same blood In both cases a moderately severe reaction followed and while the animal which had received the injection of 50 cubic centimetres was rather more severely affected than the other, the difference on the whole was but slight In all I have inoculated 12 donkeys, and, while none died, the difference in susceptibility was most clearly demonstrated, some scarcely showing any reaction at all

The susceptibility of cattle to the inoculated disease is excessively variable I have inoculated 21 cattle A definite febrile action was produced in seven cases, and four of the animals died In the case of one which died, and in which the symptoms produced were quite characteristic of those found in horses, the inoculation of its blood into a clean horse was followed by the usual period of incubation, the onset of fever, and death from characteristic horse sickness The disease known as "Imapunga" which occurs to a limited extent among cattle, presents features which in every respect are identical with those produced in susceptible cattle by the inoculation of virulent blood taken from animals suffering from horse sickness

Angora goats are also to a limited extent susceptible to horse sickness infection Of 17 which were inoculated a febrile reaction occurred in 10, none died From one of the 10 blood was taken, which was used to inoculate an ox The latter animal developed fever, and died with exactly similar symptoms during life, and showed the same post mortem conditions as the ox already referred to, the blood of which, when inoculated into a horse, produced characteristic horse sickness

Sheep are also susceptible Of 10 sheep which were inoculated six showed a well marked febrile reaction, but none died I have not succeeded in transferring the disease to rabbits, guinea pigs, rats or mice

The transmission of the disease for protective inoculation by means of the inoculation of fresh blood —The inoculation of horses with the blood of donkeys which were suffering from fever produced by inoculation has been attended with most varying results In some cases death has been produced in some an irregular febrile period, and in others no apparent result has followed The period of onset of the fever has likewise been most variable In some cases a reaction has been set up corresponding to the normal period of incubation which obtains in horse sickness, while in other cases reaction has been delayed for more than 25 days

Where fever has set in on or about the eighth day, has been moderately severe in degree and duration, and has subsequently subsided, a very definite degree of protection has been produced, although seldom high enough to set up such a resistance as to oppose death when the animal was subsequently inoculated with virulent blood

A striking demonstration of variable susceptibility among horses was furnished during these experiments Of three horses and one mule which were each inoculated subcutaneously with five cubic centimetres of fresh blood the mule had no reaction, two horses had scarcely any reaction and one horse had a good reaction In the case of the last horse when subsequently inoculated with virulent blood it suffered severely and just managed to recover The others had not been protected to any appreciable degree Obviously, therefore, the susceptibility of the last animal had been such as to admit of infection from the blood of the donkey producing reaction and the establishment of protection, whereas the higher degree of insusceptibility of the other animals resisted infection and in this way evaded the onset of protection This phenomenon forms the greatest barrier to protective inoculation and has contributed to the enormous trouble which I have experienced in devising a practical method of protective inoculation The fresh infected blood of cattle sheep and goats is still more variable in its results than is that obtained from the donkey Numerous other experiments of the same nature have been made all of which result in showing that donkeys, oxen, goats and sheep possess a very irregular susceptibility to the disease, that the blood of donkeys which do not react may produce no effect when inoculated into the horse, that the blood of donkeys which have evinced moderate reaction may produce intense reaction in some horses and practically none in others, and that a mild reaction in the donkey furnishes no definite assurance as regards the reaction which its blood may set up in horses

Owing to the variable quality of the infection possessed by infected blood of the donkey in the fresh state I experimented with blood taken from donkeys and oxen which after those which react slightly after 100 cubic centimetres of serum and one cubic centimetre of virulent blood is equal to 100 cubic centimetres of fortified serum. Moreover, as already shown, when the virus is attenuated by its passage through less susceptible animals, such as the donkey or the cow, its effect, when used in the same dose, either by subcutaneous or intravenous injection, varies very greatly in different animals; in some producing no evident reaction, in others setting up some fever, while again in others its use was followed by the onset of the virulent disease resulting in death. If, therefore, the admixture of serum with virulent blood is followed on inoculation merely by a modified form of the disease it must be concluded that the serum of itself cannot be credited with this result, but that a peculiar quality existing in the animal body and varying in amount from animal to animal must play an important part. Whether this principle is a simple body or is a combination of several bodies cannot at this moment be determined, but for convenience' sake I would suggest that the name "antagones" should be applied to it. The term need not be taken to imply either an antitoxic or a germicidal body, but merely to denote the "defensive" properties which are already existent to a greater or less degree in all animals, or are produced or increased under special stimulation. Since thoroughly "salted" animals and donkeys can be re-inoculated and infection proved to exist in their blood for at least 10 days subsequently, I am inclined to look upon the protection existing in "salted" animals as of the nature of a "tolerance," and to believe that true immunity in horses against this disease is never acquired.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PERFORATING SHELL WOUND OF THE LEFT CHEST APPARENTLY HEALED; ACUTE STRANGULATED DIAPHRAGMATIC HERNIA; LAPAROTOMY; DEATH.

BY WILLIAM EDWARD HOME,
STAFF-SURGEON R.N.

ON Oct. 28th it was reported to me that a man had been suffering for two days from constipation and colic and that he had been under treatment unrelieved for 26 hours, and I was asked to see him. It soon became clear that he was suffering from acute intestinal obstruction. The localising signs and symptoms were incorrectly interpreted and I believed that the trouble would be found to be in the right iliac fossa. I performed laparotomy, but failed to find the obstruction. The patient died on the 30th. A post-mortem examination on the next morning showed that the left lung was collapsed into the upper part of the left chest, while nearly the whole of that side was occupied by the omentum and a large knuckle of the transverse colon which had escaped from the abdomen through a slit in the diaphragm with its edges rounded, not new cut, and adherent generally to the omentum. I would note that the man lay sometimes on the injured side, but generally he sat up in bed, and he never lay down towards the end. I suppose this position relaxed the edges of the slit. The patient had been wounded at Tientsin four and a half months before by a fragment of shell which penetrated the chest and (as I was told afterwards by a friend) had not been removed. The wound was in the præcordia and had certainly penetrated the lung and probably, also, I submit, the diaphragm, the lesion in which had not healed. The external wounds were reported to be healed two and a half months before. He made almost no complaint to us, and, indeed, I had mistakenly supposed him to be well and had never at all associated the colic with his wound. That others may be warned of the risks which may attend even those wounds which are said to be healed I desire to put this case on record.

TWO CASES OF EFFUSION INTO THE SAC OF THE PERICARDIUM, WITH FATAL TERMINATION IN 24 HOURS.

BY FREDERICK WILSON, M.B., C.M. EDIN.

CASE 1.—A young married man, aged 35 years, fell into a river on Dec. 25th, 1899, but felt no ill effects from his immersion till the afternoon of the 28th, when he complained of a stitch underneath his heart and difficulty in breathing. After he had taken a little brandy this went off and he felt better, but not feeling "up to the mark" he went to bed early. About midnight he complained of great pain in the region of the heart and difficult breathing. A medical man was sent for at once, but having some distance to go he was too late, for the young man had expired before his arrival. The patient had, it seemed, become unconscious directly the messenger had departed, and he never regained consciousness. A necropsy was performed on the next day when all the organs were found to be perfectly healthy except for the presence of a little pleurisy on the left side, and when the sac of the heart was opened there was found fully a pint of fluid. In this case there was no opportunity for making a diagnosis.

CASE 2.—A young man, aged 20 years, had been enjoying himself on the morning of his birthday. He had then gone home and had partaken of a very heavy meal. His employment being a miner on the night shift, he went to bed and slept soundly till the time came for him to go to his work. On the evening of Nov. 5th, 1900, he went to work. He did not then complain of illness, but while in the pit he felt sick and had a little vomiting. Nevertheless, he went on with his work all night. When he came up to the surface on the morning of the 6th he was again sick, and when he got home, after taking some tea he vomited again. He then felt better and went to bed. On the same afternoon he became unconscious, but his mother having gone away for a fortnight's holiday assistance was not sought till 10.30 P.M. When I arrived I found him lying unconscious, gasping for breath, and sweating profusely. On careful examination I could find nothing to account for the unconsciousness, and as it was late and I had been informed about the drinking on the previous day I told his friends to keep him warm and to watch him till the morning, when I would look in early. To my surprise I found him on the morning of the 7th pulseless and evidently dying. He was still unconscious but his breathing was easier. I called in another medical man, but we discovered nothing to account for the symptoms which were present. The patient was in such a precarious condition that we did not think it advisable to turn him over to examine him thoroughly, and the omission to do so was, I think, in this case quite justifiable. The patient died on the same evening and I performed a necropsy on the afternoon of the 8th, when I found all the organs of the body healthy except that there was a little pleurisy on the left side, and on opening the pericardial sac I found about a pint of fluid.

Newtown, North Wales.

A CASE OF SPONTANEOUS EVOLUTION IN ARM PRESENTATION.

BY J. BELL, L.R.C.P. LOND., M.R.C.S. ENG.,
ACTING PRINCIPAL CIVIL MEDICAL OFFICER, GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

SPONTANEOUS evolution in arm presentation being rare the following case may be of interest.

A Chinese female, aged 28 years, was admitted to the Government Maternity Hospital having been in labour for 24 hours. The left hand and arm were presenting and were quite black. I was immediately sent for and I saw the patient about 15 minutes after receiving the summons when I found that the labour had terminated naturally. The nurse told me that there was a severe pain and then the head came down followed by the body. The child was at full term and was dead. It was a small child, but was unfortunately not weighed. The mother has had three other children; she was 5 ft. 1 in. in height and weighed 7 st. 9 lb., being about the average height and weight of women of her class.

LEEDS GENERAL INFIRMARY

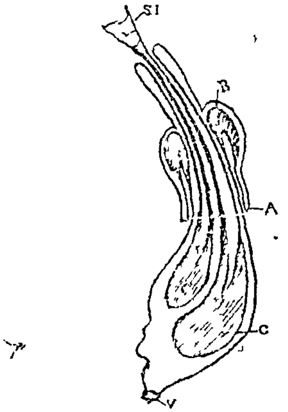
TWO UNUSUAL CASES OF INTUSSUSCEPTION

(Under the care of Mr LAWFORD KNAGGS)

IT is only within recent years that laparotomy has been considered admissible in the treatment of intussusception, but a few cases are on record in which this operation was performed with success even in pre antiseptic days Such a case was recorded in 1835 by Dr J R Wilson[1] of Mississippi, but none of these cases occurred in infants, in whom shock after abdominal operations is so very marked Laparotomy was, however, recommended many centuries ago by Praxagoras Though it is true that inflation or injection may be followed by recovery in a certain proportion of cases, as among the 103 cases collected by Dr F H Wiggin[2] of New York there were 16 recoveries with this treatment, but in the same series there were 23 deaths in cases in which inflation or injection had been employed After laparotomy 21 patients recovered and 43 died, but in most of the fatal cases injection or inflation had previously been employed in vain In the former of Mr. Lawford Knaggs's cases recorded below, the very youthful age of the patient, three months and a half, was greatly against success, though recovery has occurred at a very slightly greater age, as in a case under the care of Mr E. W Roughton[3] in which the age was four months An early record of a retrograde intussusception is that described by Spry[4] One of the most curious suggestions for the treatment of intussusception is that made by John Hunter, who recommended emetics, as he thought that the reversed peristalsis supposed to occur in vomiting might draw out the prolapsed bowel For the notes of Case 2 we are indebted to Dr O H Greenwood, house surgeon

CASE 1. *A double intussusception, laparotomy, reduction, death* —A female child, aged three months and two weeks, was admitted into the Leeds General Infirmary on August 6th, 1899, suffering from an intussusception The symptoms were the usual ones—viz, vomiting, blood stained slimy evacuations, and a tumour in the left iliac region The two former had been present for six days The apex of an intussusception could be felt in the rectum two inches from the anus Two days before admission "the seat" had come down, and after three or four minutes went back by itself This was the only occasion on which this had happened The patient's general condition seemed to be fair

The case was at once handed over by Dr. A G Barrs for surgical treatment, and soon after admission the patient was anæsthetised and the abdomen was opened The reduction of the intussusception was begun from the lower end within the abdomen The apex was gradually pushed up until the empty rectum could be brought into the wound, but it was soon discovered that no real progress was being made The tumour was therefore brought outside It was then found that a retrograde and secondary intussusception was present This had formed from a folding downwards of a portion of the outer layer of the primary intussusception Its length was between four and five inches, and its neck showed as a ring of pale gut encircling the tumour firmly about its middle (A) Reduction of the retrograde invagination was commenced from above Its accomplishment was easy at first, but there was considerable difficulty in unfolding the last three quarters of an inch owing to the swelling that had taken place at the apex (B) When the ascending invagination had been unrolled the primary one was dealt with, reduction being readily accomplished from below in the usual way. The ileo cæcal valve was the presenting part and was the most difficult to reduce On examining the bowel before closing the abdomen the peritoneal covering was found to be the subject of many longitudinal splits, and there were considerable thickening and a good deal of local peritonitis about those portions of the bowel that had formed the apices of the primary and secondary invaginations The child died suddenly four hours after the operation during an act of vomiting when apparently she had rallied satisfactorily and was going on well.



S I Small intestine A, Neck of secondary intussusception B, Apex of secondary intussusception C, Ileo-cæcal valve. V, Anus

CASE 2 *Enteric intussusception caused by an intestinal lipoma, laparotomy, reduction, removal of tumour, recovery* —A woman, aged 29 years, was admitted into the Leeds General Infirmary on April 16th for symptoms of intestinal obstruction Her illness had begun suddenly five weeks before with intense pain in the left iliac region accompanied by diarrhœa and vomiting This subsided, but from that time she had "bilious attacks" with vomiting every other day About 10 days before admission she became much worse and a medical man was called in She was very bad with vomiting, diarrhœa, and pain on April 13th, was about her work on the 14th, and bad again the day before admission Her motions had contained slime and a tarry looking substance

On examining the abdomen the left rectus was at once noticed to be more prominent than the right, and at times was raised markedly above the general surface of the parietes On manipulation a large elongated tumour could be felt extending from several inches above the umbilicus down into the pelvis It was covered chiefly by the left rectus and when palpated it became hard and more defined and the seat of pain, and these changes were accompanied by gurgling The tumour was not tender and the resonance over it was impaired On rectal examination what was thought to be the apex of an intussusception was readily felt through an intervening fold of mucous membrane

On April 17th the abdomen was opened in the median line and a large intussusception of the small intestine was found lying beneath the left rectus The apex lay at the bottom of the pelvis and the neck deep down in the upper part of the abdomen This could only be brought to the surface towards the completion of reduction, which was easily accomplished by taxis applied at the lower end in the orthodox manner It was then found that the presenting part of the intussusception had been an elastic, firm, and nodulated tumour as big as a hen's egg, which, though attached to the wall of the bowel was freely moveable within the intestine in the vicinity of its anchorage There was no congestion of the invaginated bowel or inflammation of the opposed serous surfaces, but there was a general hypertrophy of the intestinal walls both above and below the tumour aneurysm, but later dulness was noticed at the left apex. This was followed by pulsation in the second left interspace. There was some fulness in the veins on the left side of the neck and marked bronchial breathing in the left interscapular region was audible. At no time was there any inequality of the radial pulses or of the pupils. Paralysis of the left vocal cord only occurred four days before death. During the last six months of life dysphagia and the constant coughing up of a glairy viscid mucous greatly distressed the patient. At an early period of the case Tufnell's treatment was tried for seven weeks, but the patient was so intolerant of confinement to bed that it had to be discontinued. The end was preceded by severe attacks of paroxysmal laryngismus stridulus, with a cough like that of whooping-cough. In the attacks the face became purple and the surface of the body livid. On laryngoscopic examination abductor paralysis of the left vocal cord was found. Death occurred in one of the attacks of dyspnœa, four and a half years from the commencement of the symptoms. At the necropsy a tumour of about the size of a fœtal head was found lying immediately above the sac of the pericardium. The whole of the transverse and descending parts of the arch of the aorta were apparently included in the aneurysm. There were evidences of pressure on the trachea and both bronchi but especially the left and on the œsophagus. The left lung was collapsed to about two-thirds of the size of the right lung. The heart was of about normal size and depressed with its long axis lying transversely. Dr. Hall commented on the difficulty of diagnosis in this and similar cases of aneurysm in which at the onset physical signs were wanting or were very obscure. He pointed out that a harsh, clanging cough in a middle-aged man with atheromatous vessels and a history of syphilis were very suggestive of aneurysm. He laid stress on the frequency of paralysis of the recurrent laryngeal nerve, especially on the left side, and emphasised the importance of systematic laryngoscopical examination in all cases of obscure intra-thoracic mischief. This examination as a routine measure was necessary as unilateral abductor paralysis was compatible with a practically unaltered voice. Of 41 cases of aneurysm which he had seen 22 had presented hoarseness and 19 had presented paralysis of one or other vocal cord, usually the left. Dr. Hall alluded to the paroxysmal nature of the dyspnœa met with in cases of intra-thoracic aneurysm, and thought there were not infrequently attacks of laryngeal spasm. Tracheotomy was generally useless, as the main cause of the dyspnœa was direct pressure in the trachea. He regarded the diastolic shock or "thud" as the most reliable auscultatory sign of aneurysm, the presence or absence of a murmur being of comparatively small importance. He had not found tracheal tugging to be of assistance in diagnosis. The combination of loud tracheal breathing and dysphagia, pointing to pressure on the trachea and œsophagus, was, in his opinion, very suggestive of aneurysm. The most recently introduced aid to diagnosis of aneurysm—viz., the Roentgen rays—promised to be of the greatest possible assistance. In discussing the treatment of aneurysm he pointed out that the cases subjected to the Tufnell method required to be carefully selected, and he was not in favour of restricting the diet to the quantity advised by Tufnell. He had found that restriction to 10 or 12 ounces of solids and from 12 to 16 ounces of fluids was sufficient, and as much as 18 ounces of solids might be allowed, but the fluids must not exceed 16 ounces If this plan were adopted drugs should as far as possible be avoided. His experience of the treatment of aneurysm by the subcutaneous injections of gelatin was limited to one case which was not benefited by it. Dr. Hall suggested that the discussion might be profitably directed to the following points:—1. The diagnostic value of the diastolic thud in aneurysm of the aorta. 2 Was tracheal tugging ever a sign of great importance? 3. The range of the Roentgen rays in the diagnosis of aneurysm. 4. If the Tufnell plan of treatment were adopted, how long should it last and should it be continuous or intermittent? 5 What amounts of solids and of fluids were found to answer best? 6 Was it desirable to give iodide of potassium during a course of Tufnell's treatment? 7. Was there any evidence forthcoming as to the utility of chloride of calcium in the treatment of aneurysm? 8. Was Lancereaux's method of treatment by the subcutaneous injection of gelatin a safe and reliable plan? 9. For what condition should tracheotomy be advised in cases of aneurysm of the aorta?

[4] Medical and Physical Journal, No. 11

Sir WILLIAM BROADBENT said that he had seen the case to which Dr. Hall had referred to in July, 1896, and had come to the conclusion that there was an aneurysm of the third part of the aorta, although at that time there was no distinct pulsation. The principal point was the slight extension of dulness on the left of the manubrium and the reinforcement of the aortic second sound at that spot. Tracheal tugging—a sign he never failed to look for—was present and also brassy cough and unequal pulses. The jugulars did not empty on deep inspiration and there was imperfect entry of air into the left lung. He had ordered iodide of potassium. He placed no reliance upon mere symptoms as an indication of consolidation. If consolidation was taking place in an aneurysm the chief indications of this consolidation were a diminution of the diastolic shock and a modification in the ringing second sound. Murmurs were of no significance whatever in aneurysm. He had seen a parallel case as regards the physical signs, but there was no paralysis of the vocal cord. Under iodide of potassium the patient had greatly improved. He had seen him lately. The diastolic shock had disappeared. The dulness was diminishing and the aortic second sound was not remarkably ringing. As regards the points under discussion, the diastolic thud when present was absolutely diagnostic, but its absence in aneurysm of the second or third part did not nullify other physical signs. Moreover, it might disappear when consolidation had taken place. The tracheal tugging was of more interest than importance in his opinion. Skiagrams might undoubtedly be useful in those lesions which were not accessible to physical examination, but he had not yet seen a case in which they had achieved or contradicted a diagnosis made by other means. Turning to the question of treatment, he believed that iodide of potassium answered every purpose and rendered what was called Tufnell's treatment unnecessary. He had never found this extreme curtailment of fluid indispensable. The great opportunity for successful treatment came, not in the early stage of an aneurysm, but later, when its orifice had become narrowed; consequently treatment which had previously failed might be successful later. He had had no experience of calcium chloride or of gelatin. As to tracheotomy, it was of no use when the trachea was directly pressed upon, but free bleeding afforded the greatest relief to breathlessness and pain, and he referred to a case in which the patient had lived for many years afterwards.

Dr. HUGH WALSHAM referred to a case of aneurysm in the Victoria Park Hospital in which the heart was lying transversely in the thorax, in which the Roentgen rays had enabled them to make a diagnosis. This procedure was certainly useful in aneurysms of the transverse and descending arch. He also referred to another case of a woman who was thought to have only aortic regurgitation and who presented no symptoms or signs of an aneurysm which was revealed by means of a skiagram.

Dr. ROBERT MAGUIRE wished again to ask whether anyone had seen a case of aneurysm occurring in the labouring man absolutely cured so that he could return to his work. It was undoubtedly true that those who did light work could be cured in this sense but he doubted if labourers could be restored to this extent. He had seen several cases in which he believed that the constant pressure of an aneurysm upon the œsophagus and trachea which resulted from a patient habitually lying on his back produced a tendency for the aneurysm to burst into these passages. He wished particularly to refer to the results of Lancereaux's treatment. He had treated four cases in this way all with good results. He could not enter into all the details but there was no question that consolidation had been brought about in these cases. The first presented a cough, alteration of voice, paralysis of the left vocal cord, dilatation of the heart, a systolic murmur both at the aortic orifice and at the apex, the cardiac apex being situated in the axilla. After the third and fourth injection there was a marked alteration in these cases. The cardiac murmurs had disappeared, the heart had gone back into its right place, and the area of dulness had diminished. The second and third patients also showed great improvement both in the sound of their voices and in other symptoms. The fourth case showed an improvement in the area of dulness and a great relief in the pain which affected the sixth to tenth intercostal nerves. His method was to inject 100 cubic centimetres of absolutely sterile gelatin of a strength of 2 per cent. made up with seven per 1000 chloride of sodium solution. It must be injected into the intra-muscular tissue and he preferred the buttock, avoiding the sciatic nerve. The skin could be frozen with methyl chloride and the needle could be introduced at least two inches into the muscle Everything must be absolutely sterile. This was a point of the greatest importance. He had had considerable difficulty in finding a description of Lancereaux's methods.[1] Critics had said that the method was not so successful in other hands as it was in those of Lancereaux, and this he thoroughly believed, probably because of the want of care in its execution. He began by doubting the efficacy of the method, but he thoroughly believed in it now. His practice was to give four injections on four consecutive days, then to wait for two weeks and repeat the injections, and then to wait for a further period of time. The question as to whether the treatment was quite safe he was not prepared to answer, but there was no doubt that thorough asepsis and many little points of technique were of the highest importance, and undoubtedly there were several sources of risk of tetanus and sepsis such as might occur in all surgical procedures.

Dr. R. SANDERSON (Brighton) remarked that the Tufnell treatment was certainly not suitable for neurotic persons. The patient referred to by Dr Hall had spent his time in studying the anatomy of the thorax and calculating in which direction his aneurysm would burst. Neurotic cases, he believed, were much better moving about.

Dr. OSWALD A. BROWNE had had the opportunity of making necropsies on a large number of cases at St. Bartholomew's Hospital. In nine out of 35 cases of aneurysm of the aorta the swelling arose from the posterior wall of the transverse portion, and 15 out of 35 compressed the trachea. Five of them compressed the œsophagus also. This went to show how frequently the lesion affected the transverse arch and projected backwards. Death frequently resulted from pressure upon the trachea He did not think that the recurrent laryngeal nerve was so frequently affected. In only three out of the 35 cases was it involved. He referred to a case of aneurysm with slight dulness in front of the sternum. Examination of the larynx showed no signs, but a few days later the patient was attacked with a severe paroxysm of dyspnœa. This was temporarily relieved by bleeding, but the dyspnœa was repeated each day and he died upon the fourth day, and an aneurysm no larger than a tangerine orange was found compressing the trachea Aneurysm of the descending part of the arch generally made its way into the left interscapular space and often obstructed the œsophagus. There was a difficulty in carrying out Tufnell's treatment. He mentioned a case of aneurysm of the abdominal aorta treated by calcium chloride. The man was about 35 years of age; an aneurysm of about the size of a cricket ball could be made out in the abdominal aorta. He was attacked by severe abdominal pain He remained in hospital at rest and was put upon 20 grains of calcium chloride, gradually increased to 30 grains, three times a day. He went out completely well, and when seen two years subsequently was still carrying on his occupation of a tramway conductor.

The discussion was adjourned to Dec. 10th.

CLINICAL SOCIETY OF LONDON.

Thrombosis of the Inferior Vena Cava.—Syphilitic Pyrexia.—Subsequent History of Nine Cases in which the Spleen had been Removed.—Nephritis without Albuminuria.

A MEETING of this society was held on Nov. 23rd, Dr. W. CAYLEY being in the chair

Dr. SIDNEY PHILLIPS narrated a case of Thrombosis of the Inferior Vena Cava, Iliac, and Femoral Veins of acute onset and fatal termination, with symptoms resembling those of perforated gastric ulcer The patient was an anæmic maid-servant, aged 19 years, who had suffered from slight symptoms of indigestion She was suddenly seized with pain in the abdomen, vomiting, and collapse, accompanied by a temperature of 103° F Soon after this (on Dec. 6th) there were swelling and pain in the region of both parotid glands, but this cleared up Next (on Dec. 9th) she was taken with cramping pains and thrombosis of the deep veins in the left calf. Finally, there was swelling (œdema) in the whole of the left lower extremity, followed by abdominal pains and thrombosis in the portal system. Throughout the temperature was not elevated except on the first occasion. The patient died from exhaustion. At the necropsy extensive thrombosis was found in the inferior vena cava and iliac veins and the veins of the left lower extremity. No local or constitutional cause for the thrombosis could be discovered and Dr. Phillips regarded it as a case of primary infective thrombosis. This case showed that parotitis was not, as often stated in text-books, distinguishable from mumps by being unilateral and suppurative —Dr. CAYLEY asked if an examination of the clot in the inferior vena cava had been made.—Dr. SAMUEL WEST referred to a case which he had reported some years ago which resembled Dr Phillips's case in some particulars, only there were no abdominal symptoms suggesting perforating ulcer. The patient was a young girl who was taken with pain in the abdomen followed by swelling of the legs. Shortly afterwards the urine contained a good deal of albumin. This was followed by an attack of shivering accompanied by ascites, indicating thrombosis of the portal system. She died and at the necropsy a clot was found in the inferior vena cava, portal system, and veins of the legs. The thrombus apparently originated in this case from one of the pelvic veins in which a thrombus of older date was discovered.—Dr PHILLIPS, in reply, said that no bacteriological examination of the clot had been made because in the course of the necropsy the vena cava had been injured by the knife, and it was thought useless afterwards to make cultures.

Mr. CAMPBELL WILLIAMS reported a case of Late Syphilitic Pyrexia (intermittent essential fever of syphilis). The patient was a man, aged 43 years, who contracted syphilis in December, 1896 He had the usual sore, enlarged glands, and secondary symptoms. After this he had suffered little with the exception of a sore tongue, which was irritated by an ill-fitting denture. This was quite healed by June, 1898, and he had no further symptoms. He was treated with mercury mainly, alternately with iodides, for a period of two years, and was free from all symptoms for 18 months before ceasing attendance. In January, 1900, he had influenza, and in April he was reported to be very ill from post-influenzal intermittent fever, for which he was being treated with quinine and arsenic. Mr. Williams saw him on April 18th. He had periostitis of the right clavicle and pyrexia. His temperature rose every afternoon and the crisis came in the small hours of the morning. Syphilitic fever was diagnosed, he was put upon mercury, and on April 25th his temperature became normal and had remained so ever since. He was now quite well —Dr. PHILLIPS remarked that such cases were by no means uncommon, and he referred to one which was recorded in the Transactions of the Medical Society of London. In another case which had been under his care a woman who had contracted syphilis 10 years previously developed pyrexia which might be mistaken for malarial fever. He thought that such cases were commoner than was generally supposed. They were apt to be confused with tubercle or to be mistaken for quartan or tertian ague. Some years ago a case had been reported by the late Dr. J. S. Bristowe in the Transactions of the Clinical Society of London of a man who was affected with intermitting pyrexia of obscure origin until on one occasion, when the eyes were being examined, syphilitic choroiditis was discovered. Mercury was then administered and the patient got well —Dr. T. D. SAVILL agreed that these cases were not uncommon and he was surprised that this fact had not found its way into text-books. He was house physician when the case referred to by Dr. Phillips was under Dr. Bristowe's care, and he believed that the drug used was iodide of potassium, not mercury. He commented on the sudden subsidence of the temperature under mercury in Mr. Williams's case, remarking that in his experience the temperature did not fall as rapidly under mercury as under iodide. He recalled a rather remarkable case seen by him at the Croydon Hospital—that of a lad, aged 15 years, who was supposed to be suffering from pernicious anæmia He had an intermittent temperature and this lasted for about nine months, when he died. Post mortem they found very extensive endocarditis and endarteritis, and on opening the skull they alighted upon a large gummatous mass stretching across the frontal region. The clavicle was also involved and striæ were seen in the cornea.—Mr. CHARTERS SYMONDS took exception to the term "essential fever." He thought that in such cases there was always a periostitis or some gummatous deposit which might or might not be discovered but which always acted as a cause for the constitutional disturbance.—Dr. CYRIL OGLE was not quite sure whether the cure by mercury was sufficient evidence to prove such cases to be syphilitic. He referred to a case which he had seen in St. George's Hospital of a patient who had suffered from pyrexia for eight weeks before admission and eight weeks while in hospital. Every second or third day the temperature went up to 103° or 104° F., accompanied by headache, sweating, and sometimes vomiting. Treatment by quinine and arsenic was without effect and repeated examination revealed no cause. Administration of creasote in this case was attended by a disappearance of the fever and he suggested that the pyrexia was probably due to intestinal sepsis arising from some abnormal fermentation within the intestines. Possibly mercury would have the same effect as an intestinal antiseptic.—Mr. WILLIAMS, in reply, said that he had used the term "essential fever" in contra-distinction to that which appeared with the initial rash of syphilis. In regard to the treatment he believed that such cases reacted more quickly to mercury than when treated by iodide. One of the interesting features in this case was the thorough treatment by mercury during 18 months to which the patient had been previously submitted.

---

[1] Our readers will find an account of the method in THE LANCET, vol. ii., 1898, pp. 1092, 1294, 1309.—ED. L.

Mr. J. BLAND-SUTTON reported the details of a case in which he had performed Splenectomy for an Enlarged and Wandering Spleen in a woman, aged 34 years. The patient, already the mother of seven children, was two months pregnant at the time of the operation; the abdominal wall being very lax from repeated pregnancies allowed the spleen to tumble freely about, and this caused much inconvenience and pain. The operation was carried through without difficulty; the patient quickly recovered and left the hospital 18 days after the splenectomy. Her subsequent health had been very good. Mr. Bland-Sutton remarked that since 1892 he had performed the operation of splenectomy on nine occasions, two of the patients having died. One was a malarial case with intense leucocytosis and one was a case of malignant disease. Seven of the patients were living and he had taken some pains to ascertain that they were still in a condition of good health. Four of the operations had been done for wandering spleen. Two of them were for curious enlargement unattended by any increase either in the red or white blood corpuscles. In one the spleen had been removed because it was torn during an operation performed for a large abscess the base of which consisted of the capsule of the spleen. One of these cases was particularly worthy of comment. The patient was tuberculous and was transferred from the Brompton Hospital to the Chelsea Hospital on account of a lump in the abdomen which was diagnosed as a wandering spleen. The patient had a cavity in the lung and he (the speaker) was doubtful about performing the operation of splenectomy because in two or three of the recorded cases patients had developed lung disease subsequently to the operation. However, splenectomy was performed and the patient made a good recovery. The spleen, which had been removed, was found to be filled with miliary tubercle, the nodules having been examined by Mr. A. G. R. Foulerton and found to contain tubercle bacilli. The operation had been performed three years ago, the patient remaining well for some time, but at the present time the lung disease was again becoming active. In all the seven cases repeated observations had been made upon the number of red and white blood-corpuscles with great care and no alteration had been discovered in the blood. Indeed, anyone examining these patients would never suspect them to be spleenless.—Dr. CAYLEY remarked that it would be interesting at the necropsy of Mr. Bland-Sutton's cases to see what had made up for the loss of the splenic tissue.—Dr. PERCY KIDD asked if there was much hæmorrhage during the operation. He referred to a patient suffering from leucocythæmia on whom an operation had been performed upon the kidney, on account of pyuria, in spite of the presence of leucocythæmia. Such cases were often attended by considerable hæmorrhage.—Dr. A. F. VOELCKER asked if an accessory spleen had been discovered in any of the cases. If so this would afford an explanation of the absence of changes in the blood in Mr. Bland-Sutton's case. He had made a post-mortem examination on one case in which the spleen had been removed one and a half years previously. There was no accessory spleen in this case and the patient eventually died with syphilitic disease of the liver.—Mr. BLAND SUTTON, in reply, said that he always avoided operating in cases of leucocythæmia. Since his first operation an average of about six cases per annum of enlarged or wandering spleen had been sent in for operation, but if an examination of the blood showed leucocytes they almost invariably died from leucocythæmia within from three to 18 months. His rule was that if the proportion of white corpuscles did not exceed 20 to the 1000 splenectomy might be performed. He referred to a patient, aged 26 years, who had an abdominal tumour which was thought to be malignant disease of the spleen. The proportion of white corpuscles in this case was 20 to the 1000, and although it might be regarded as an early stage of leucocythæmia it was decided to explore. The operation was successful, although there was a little more hæmorrhage than usual; but at the end of 48 hours the patient developed some curious nerve phenomena and the stomach seemed to indicate acute dilatation. She died within 24 hours. There was nothing to indicate hæmorrhage. The case was a private one and a necropsy was refused. During operation he had always looked out for an accessory spleen so as to leave it behind if it were present. He had hunted up one of the late Sir Spencer Wells's old cases—a young woman upon whom splenectomy had been performed 15 years before. He (Mr. Bland-Sutton) had found her to be in good health though she was of slender build.

Dr. W. P. HERRINGHAM communicated a case of Nephritis without Albuminuria. The patient, a boy, aged nearly four years, who was admitted into the Children's Hospital, Paddington-green, for diarrhœa and vomiting on March 29th, 1899, was supposed to be cured, and was sent to the convalescent home of the hospital on May 5th. While in the ward the urine was thrice examined and was found to be natural. The amount was normal. There was no previous history of scarlet fever. From May 5th to July 14th the patient was in good health at the convalescent home, which was visited regularly by the resident medical officer, and where the children were kept under constant supervision. There was no case of scarlet fever at the home. On July 14th dropsy began in the feet and spread to the legs and face. The urine was not albuminous. The patient was sent back to the hospital and for the next six weeks he formed a typical picture of subacute nephritis, but without ever showing any albumin in the urine, which was exceedingly scanty in amount. No formed elements were ever visible under the microscope. On August 29th he died. At the necropsy (made by Dr. L. G. Guthrie) the viscera, including the kidneys, appeared natural. Microscopical preparation (made by Mr. A. E Turner) showed cloudy swelling in a few of the convoluted tubes and albuminous plugs in a great many; in a few of the collecting tubes similar plugs were found. An exudation, apparently of serum or albumin was found in almost all the glomeruli, and there may have been some cellular increase in the capillary tuft. As the child was under hospital observation for three and a half months before the onset scarlet fever might be excluded. The case was believed to be unique. Several cases had been recorded of nephritis without albuminuria following scarlet fever, but though it had been suspected to occur without scarlet fever the condition had never been proved by post-mortem examination. Why the anuria should be so extreme he did not understand.—Dr. WILLIAM EWART asked for details as to the symptoms in this patient and what treatment had been adopted. In some cases of dropsy he had seen very good results from acupuncture and the administration of quantities of water to drink. As soon as the serum exuded from the punctures the urinary secretion was increased and its specific gravity improved. He regarded Dr. Herringham's case as an illustration of a special disease not yet described.—Dr. F. E. BATTEN had seen two or three cases resembling the one narrated. One was that of a child, about four or five years of age, who passed very small quantities of urine, containing very little urea of low specific gravity, attended by generalised œdema. The patient recovered. Another case presented œdema exactly like albuminuric cases. The patient passed urine of low specific gravity containing very little urea The child died and at the necropsy he thought that the kidneys were rather small for the child's age, but the microscope revealed no change of any kind.—Dr. JOHN FAWCETT asked what evidence there was of the exudation in the glomeruli being of an albuminous nature.—Dr. WEST remarked that the condition was not unknown in infancy and in children under two years of age. They presented dropsy and all the symptoms of renal disease. Nevertheless, careful examination revealed neither albumin nor other abnormality in the urine. He had seen several cases but they all got well. He was not satisfied that the dropsy was of renal origin.—Dr. HERRINGHAM, in reply, said that he felt some doubt as to the renal nature of the disease though it had all the symptoms of it. The patient had had no anæmia previously. The œdema was the first symptom and it spread rapidly upwards from the legs. He felt no doubt about the nature of the changes in the kidneys which he had described. They had been seen by others. As regards the treatment by acupuncture he had never seen a patient recover when treated by this method.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Mental Disorders dependent on Toxæmia.—The Use and Abuse of Travel in the Treatment of Mental Disorders.—Application of Electricity in certain Forms of Mental Disease.

A MEETING of this association was held on Nov. 21st, Dr. FLETCHER BEACH being in the chair.

Sir DYCE DUCKWORTH having read a paper on Mental Disorders dependent on Toxæmia (a full report of which appeared in THE LANCET of Nov. 24th, p. 1475) a discussion followed.—Dr. F. W. MOTT paid a high tribute to Sir Dyce Duckworth for his paper and referred to the selective actions of different poisons, instancing in this respect strychnia in its effect upon the spinal motor neurons. He thought that an important contributory factor in the production of insanity which had not been mentioned by Sir Dyce Duckworth was strain, and to this Professor Edinger had called marked attention and had proved that it was a factor in the causation by experiments upon animals. He also mentioned haschish poisoning in Egypt as one of the toxæmic causes of insanity.—Dr. G. H. SAVAGE said that he felt that what delirium was to the general physician acute mania was to the alienist. In consequence of a remark by Sir Samuel Wilks many years ago that one would expect the neurotic person to be more liable to delirium than another, he tried to find out whether that was the case, but at the fever hospitals he found that in many instances no inquiry had been made into the history in this respect. He agreed in the probability that a large number of puerperal cases had a septic origin.—Dr. EDWIN GOODALL said that in some cases of delirious mania bacteria had been found, including staphylococcus pyogenes albus and a diplococcus which corresponded with Fraenkel's pneumonia coccus. Animal experimentation laboured under so many disabilities in this country that little was to be expected, but he suggested that the ecchymoses seen after convulsions might be examined for organisms. He once read in a German paper that malaria was conducive to the cure of mental conditions, and one German physician suggested that asylums should be built on malarial sites. He remembered reading that in one Italian hospital in Constantinople good results in mental disorders were obtained by injection of anti-streptococcic serum.—Dr. CHARLES A. MERCIER said that the interesting point was that toxæmia was the only agent which they were sure would produce insanity—that is to say, it was the only agent by which they could produce insanity at will. Alcohol was a case in point and the insane manifestations corresponded with the amount of alcohol administered. With regard to heredity, how could they trace hereditary predisposition? how could they recognise it? He thought that Dr. Mott would admit that strain had only a localising influence. He rather looked upon the transmitted heredity as an inability to resist and eliminate toxic products. Insanity affected not only the brain but the whole man, and any derangement might be contributory to the mind disease.—Mr. J. F. BRISCOE pleaded for greater attention being paid at hospitals to the alimentary canal and the examination of the motions of patients in the same way as attention was given to urine.—Sir DYCE DUCKWORTH, in reply, said that he took it that the effect of strains was simply to produce a *locus minoris resistentiæ* and that determined the part where the toxin had effect. The question of inheritance of tendencies from parent to child concerned them very deeply and was a matter of enormous importance. He urged his hearers not to dogmatise too much yet and not to say now that all insanity was toxæmic, although it might hereafter be found to be so. Certainly toxæmia played a very large part in insanity and it was on that subject that his contribution had reference.

Dr. G. H. SAVAGE read a paper on the Use and Abuse of Travel in the Treatment of Mental Disorders. He said: As I have found that travel is being ordered for nearly every form of mental disorder it seems to me time to consider whether this all but universal remedy is beneficial or not. First I would consider the reasons for sending persons of unsound mind away for voyages and similar expeditions. Many are sent away simply to get rid of them, as they become very trying both to friends and relatives as well as to the general practitioner; next they are sent away in very many instances to avoid certification. The magisterial interference, though safeguarding the medical man, leads to the inconsiderate removal from home of many patients. Lastly, some patients are sent away for their real medical treatment, and these cases I divide into two groups: those who from general reasons would be sent away—for example, patients who cannot winter in our climate and who in addition have become deranged—and the second group contains those who are sent to distract them from their morbid mental ideas. The medical man is in the habit of ordering for patients what suits himself; hence some medical men who are not good sailors avoid sending patients to sea, while others who are fond of the sea send many on the water. I think that for slight disorders of mind following some local cause, such as love disappointment or domestic grief, travel is good; for the confirmed hypochondriac I do not think it does any good. The cause of the disorder must modify the treatment to some extent. I do not think that melancholia is benefited in many cases by travel. The danger of suicide is increased and I do not think that the forcing of varying fresh sensory impressions on such patients is for their benefit. I believe travel to be useful to many convalescing patients, but here, too, the danger of suicide has to be faced. Those suffering from delusional insanity had better not be sent on voyages—every fresh impression gives rise to fresh suspicion. In conditions of apathy and partial dementia such as follow toxic and similar conditions, taking influenza as a type, the patients are often cured by travel. Probably the most difficult cases to advise upon are those of general paralytics in their earlier stages, for then the friends will not believe that patients so vigorous and so buoyant can be on the road to a fatal malady. They think that removal from the causes of excitement must do good. Again, in the stages of remission many such patients are sent abroad; I can only say that this is done at great risk and I have seen such misery follow that I cannot advise it. I only strongly advise travel when emotional causes have caused emotional disorders of slight degree, when patients are apathetic and neurasthenic, and when they are convalescing from mental disorders. I strongly oppose such treatment in active melancholia and general paralysis of the insane. I have only time to hint at the methods of travel but I would insist upon it that sea voyages are only suitable to a small number of persons and that long railway journeys are good neither for the sound nor the ailing.—Sir HERMANN WEBER agreed that there were dangers in long sea voyages for the insane. Three intimate friends of his had been sent—by others—on long sea voyages. One, an only daughter, suffered from grave melancholia and was sent to sea with an attendant. One of the other two had two attendants and a medical man. Two of them killed themselves on the way by jumping overboard. The third repeatedly tried it, but as he had a medical man and two attendants he was prevented. But he had seen much good result from sea voyages in great mental depression, as in the case of students, and in depression caused by shock. Long sea voyages after influenza, also, he had found beneficial, and with that he understood Dr. Savage to agree. He instanced one case of insanity in a botanist who, in travelling about Switzerland for his health, encountered another botanist who showed him rare ferns, and the result was that his interest was awakened and he was restored to health. In conclusion he referred to a coachman who was mentally deranged. Dr. Savage had the courage to recommend that he be allowed to drive again and the result was his cure.—Dr. E SYMES THOMPSON said that he agreed that long voyages should not be undertaken after the borderland of insanity had been passed; but there were very many cases which stopped short of that where, however, serious mental trouble was threatened which derived great good by voyages. If mental disease was largely a matter of defective power of elimination, surely the value of changed surroundings and climate was great in increasing the eliminative power. He spoke approvingly of Egypt as a health resort owing to the pure desert air and the new surroundings, especially from an archæological point of view.—Dr. ROBERT JONES spoke against the habit of sending general paralytics abroad and gave instances in which the patients had to be sent for back again as they were in such a pitiable condition. He asked Dr. Savage to refer in his reply to the systemisation of the delusions. Dr. Savage had suggested that he (Dr. Jones) should travel with a man who had a particular form of insanity associated with delusions, and when they got some distance on the voyage the man had the delusion that his trouble was due to the medical man and refused to go an inch further. The question of elimination was very important with regard to toxæmia and therefore with regard to insanity. He had derived very great pleasure, indeed, from the contributions of Dr. Savage and Sir Dyce Duckworth.—Dr. L. A. WEATHERLY said that he felt that the question of sending patients for a change of air and scene could not be dealt with generally, but each case must be taken on its own merits. A mode of treatment which was beneficial to one patient might be absolute cruelty to another.—Dr. SAVAGE, in reply, thanked the speakers heartily for taking part in the discussion. Sir Hermann Weber's experience corresponded with his own. When he suggested that Dr. Robert Jones should go away with a patient he (Dr. Savage) had not developed his present opinions. He had suggested the propriety of one lady travelling because she would not go out of doors otherwise.

Dr. H. LEWIS JONES, in a paper upon the Application of Electricity in certain Forms of Mental Disease, said: The treatment of patients with any form of mental failure is not a thing which comes very frequently before one who is engaged in general practice, but from one or two cases which I have had to treat and also from general considerations upon the therapeutic effect of electricity I am extremely glad to have an opportunity of bringing before this meeting certain claims which electricity seems to have for use in the treatment of the insane. The most important development of electricity in the last 10 years has been in the direction of general electrification for general effects, and this line of treatment has had the advantage of being very carefully worked out by a physiologist who is not at the same time a medical man, Professor D'Arsonval. He has shown what a profound effect can be produced upon the general nutrition of the body in this way and has established by measurement the increase of carbonic acid, of body heat, and of urea in animals and in people submitted to general electrification. Clinical experience has also demonstrated the immediate effect which follows general electrification in various forms of debility, and from a consideration of these points I have for long felt that certain forms of mental failure ought to be eminently suitable for treatment in this way. [Dr. Jones here exhibited and demonstrated the simplest modes of setting up general electrification and the electrical bath treatment.] I would recount the following cases. The first was a case in which a patient after influenza lost his memory, became very weak and feeble, and was referred to me by a medical man as showing signs of progressive dementia. In a short time under simple electrical stimulation the patient became completely well. The next case was one of a journalist who completely broke down from overwork and who became unable to attend to business, and entirely altered in his manner and was so strange that on one occasion he was brought home by the police who found him wandering at large. Under suitable treatment by the electrical bath his symptoms all gradually subsided and he became perfectly well and resumed his duties. The third case is of somewhat the same type—viz., the case of a middle-aged man showing increasing inability to do his work or even to get about London as he used to do. He could not walk well; he fell down frequently, and his mental condition was dull and stupid. Under treatment by the electrical bath he has continued to improve up to the present time and he remains under treatment. These patients have all been treated with the electrical bath and the sinusoidal current taken from the mains of the Electric Lighting Company; the effect is simply that of general stimulation under which the appetite improves and the patient gains weight and sleeps better. These cases, which I hope will be supplemented by the recital of a series of instances of people who were definitely insane and treated by Dr. Robert Jones, should go far to support the belief that general electrification can be of very decided service in those forms of mental disease in which a failure or defect of nutrition is the important factor.—Dr. ROBERT JONES then detailed his favourable experience of the electrical bath treatment.—Dr. GOODALL also gave the results of his experience in the same direction. In neurasthenia his experience had not been a long one, but of nine cases five were decidedly improved. The cases in which he had looked for improvement were stuporous cases and chronic cases in which the patients had run down in health.—Dr. ROBERT JONES asked whether the beneficial effects of the water of the bath could be separated from the effect of the electricity, so that they could form an estimate of the value of each.—Dr. LEWIS JONES, in reply, said that it was difficult for him to separate the two factors in the bath, but he had had ample evidence of electricity without water producing increased metabolism and beneficial results. His own experience in reference to mental disorders was necessarily small, but those cases which had come under his notice had been much benefited by the treatment which he had outlined.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Sub diaphragmatic Abscess complicating Typhoid Fever.—Intussusception of the Vermiform Appendix.—Haab's Electro magnet.

THE fourth ordinary meeting of the session was held on Nov. 22nd, Mr. EDGAR A. BROWNE, the President, being in the chair.

Dr. C. J. MACALISTER and Major R. ROSS, I.M.S., brought before the meeting two cases from the Tropical Ward of the Royal Southern Hospital. The first was a case of Æstivo-Autumnal Fever in which the daily exacerbations had been severe, the temperature registering from 106° to 107° F. in spite of the administration of large doses of quinine. After the administration of two doses of Warburg's tincture the attacks entirely ceased for nearly three weeks. The case was of peculiar interest in that it presented retinal hæmorrhages (the so-called malarial amblyopia), the result of plugging of the retinal arteries with the malarial parasites. The other case was one of Dysenteric Ulceration throughout the whole length of the Colon, from which absorption had taken place, and the patient died from a consequent septic pneumonia. The diagnosis was rendered difficult owing to the absence of diarrhœa or other definite intestinal symptoms.—Major ROSS remarked with reference to the first case that the infection was one by the æstivo-autumnal parasites and that the punctiform retinal hæmorrhages were an example of similar hæmorrhages often found in the cerebrum and meninges in pernicious paroxysms due to this organism. With regard to the second case he stated that there was leucopenia and that doubtful amœbæ coli had been found in the stools—doubtful because the stools were old when examined. He questioned whether there was such a condition as malarial dysentery, properly speaking, but thought that cases attributed to such were due to the concurrence of the two diseases.—Mr. R. J. HAMILTON did not consider that the diagnosis "malarious amblyopia" was borne out by the charts of the field of vision and the description given by Dr. Macalister. There were retinal hæmorrhages evidently, as there might be hæmorrhages anywhere in such a pernicious condition of the blood, and the central scotoma was due to a centrally situated hæmorrhage. But the vision as recorded and the perimetric chart were not those of a toxic amblyopia, which would show evidences of a retro-bulbar neuritis, and a subsequent optic nerve degeneration might be looked for.—Dr. A. S. F. GRUNBAUM remarked that since the discovery of the bacillus of dysentery by Flexner and by Kruse the serum diagnosis of this disease, which had already been shown to be possible, should be resorted to in doubtful cases. The cultures necessary for this method were in Liverpool.

Dr. R. CATON and Mr. THELWALL THOMAS contributed notes of a case of Sub diaphragmatic Abscess complicating Typhoid Fever. The patient, a male, aged 32 years, suffered from enteric fever with defervescence on the twenty-fourth day. He was allowed to get up on the forty-third day, when the temperature at once rose. He was kept in bed for six days and again allowed to get up, when he had a rigor and there was a rise of temperature. No cause could be ascertained until a fortnight later, when a dull area was percussed at the base of the left lung, and with an exploring syringe greenish-yellow purulent fluid was withdrawn from what was thought to be the pleural cavity. An incision was made immediately, a portion of the eighth rib was removed, and a normal pleura was opened. The diaphragm was very near to the ribs and was elevated, and on palpation a hard rounded area could be made out under it. The costal pleura was sutured to the diaphragm, and on incising the diaphragm a firm convex, apparently bony, mass was exposed, through which the knife could not enter except at a small area half an inch in diameter, whence a pint of pus escaped from a cavity five inches in diameter the walls of which were one-eighth of an inch in diameter and firmly calcified. Portions were taken away by bone forceps, but the free oozing of blood forbade further removal and drainage-tubes were inserted. The pus when examined bacteriologically demonstrated the bacillus typhosus in a greenish fluid consisting of fatty granules, cellular débris, and cholesterin. A month later further portions of the eighth rib and four inches of the ninth rib were excised, and on freely incising the diaphragm the remains of the calcified wall were rapidly excised and they proved to be adherent to the liver, the spleen, the stomach, the transverse colon, and the omentum. The recovery of the patient was uninterrupted. The origin of the abscess was unknown; it must have been of a chronic nature, and probably resulted from a liver abscess or a suppurating hydatid cyst which had become recently re-infected with typhoid bacilli.

Mr. KEITH MONSARRAT read a note on Intussusception of the Vermiform Appendix and described the case of a boy, aged four years, who suffered for a month before admission into the Children's Infirmary from acute pain in the right side of the abdomen coming on in paroxysms. When first seen there was intussusception in the region of the transverse colon. At the operation which followed this was found to be secondary to an intussusception of the appendix vermiformis into the cæcum. Both primary and secondary intussusceptions were disinvaginated and the boy made a good recovery. Only on one occasion during the five weeks before operation was any blood passed by the bowel and there was no vomiting at any time. The other recorded cases of the condition were analysed and the symptoms were discussed. Two types of invagination were distinguished, one analogous to ileo-cæcal and the other to ileo-colic invagination in respect of anatomical relations. The development of secondary invaginations was also considered. With regard to treatment he limited himself to the consideration of the best method of dealing with such an intussusception where it was irreducible.—Dr. GRÜNBAUM had never during a series of experiments on peritonitis observed peristalsis in the appendix vermiformis, and he considered that it was improbable that invagination could occur as the result of its movement.

Dr. EDGAR STEVENSON described and demonstrated Haab's Electro-magnet for the removal of pieces of iron or steel from the interior of the eye. This instrument, invented by Professor Haab of Zürich, marked a complete revolution in the unsatisfactory treatment by the small electro-magnets of those serious accidents in which the eye contained a foreign body. With it a particle of iron or steel could be drawn from any part of the injured eye (by merely approaching the eye to the point of the instrument) into the anterior chamber, whence it was easily removed. The instrument was bi-polar, about two feet long, 18 inches in diameter, wound in two sections each containing about 2000 turns of insulated copper wire. It was energised by the city mains at 230 volts and took a maximum current of six ampères, thus giving a total force of about two-horse power and a lifting capacity of about half a ton. Dr. Stevenson demonstrated the lines of magnetic force, showing how long and straight they were compared to the short curved lines given off from Snell's electro-magnet; he also showed a piece of steel being acted upon in a tube of gelatin. The instrument would probably be successful in extracting needles, &c., from other parts of the body.—Mr. THOMAS H. BICKERTON added his testimony to the value of Haab's magnet, and referred to a communication made to the *British Medical Journal* of September, 1898, by Dr. Reginald Bickerton, recording the experience gained of the use of this magnet in Professor Fuchs's clinique in Vienna—viz., "Since this magnet has been in use it has never failed to extract a splinter of iron or steel from the interior of the eyeball, no matter how deeply it had been imbedded."

EDINBURGH OBSTETRICAL SOCIETY.

Election of Office-bearers.—Presidential Address.—Extraversion of the Bladder.—Cleidotomy.

A MEETING of this society was held on Nov. 14th, Dr. R. MILNE MURRAY, the President, being in the chair.

The following office-bearers were elected for the current session:—President: Dr. R. Milne Murray. Vice-Presidents: Senior—Dr. S. Macvie (Chirnside); Junior—Dr. F. W. N. Haultain. Treasurer: Dr. William Craig. Secretaries: Dr. J. Haig Ferguson and Dr. William Fordyce. Librarian: Dr. Haultain. Editor of Transactions: Dr. N. T. Brewis. Members of Council: Dr. J. Halliday Croom, Professor J. A. C. Kynoch (Dundee), Dr. James Ritchie, Dr. T. Farr Armour, Professor A. R. Simpson, Dr. J. W. Ballantyne, Dr. G. P. Boddie, and Dr. J. Lamond Lackie.

Dr. MILNE MURRAY delivered his *Presidential Address*. He alluded to the development of obstetric knowledge and its association with primitive religions. In early times and in primitive peoples the practice of obstetric knowledge would naturally be confined to women. In natural labours their duties would be simple and routine. At first friends and neighbours would perform the kindly office, but soon a separate class would spring up whose special aptitude or experience would inspire the parturient woman with greater confidence. But though the birth of a child was of daily occurrence in a primitive community, yet the progress of pregnancy and labour were shrouded in inscrutable mystery. This mystery and the danger attached to the reproductive process led them to invoke the aid of their primitive religion. The husbandmen noticed the changes in the life, decay, and regeneration of the vegetable world and to them the sun-god was the revivifying influence and the object of adoration. The worship of the generative principle was also present with the shepherd as he noticed the processes of birth, growth, and decay among his flocks and in his family. In various ways and in different localities this idea found special expression in the worship of the sun, the tree, the serpent, and the phallus. These consisted fundamentally in the invocation or propitiation of the generative or procreative principle. Hence arose shrines and temples to tutelary deities where their help could be secured by prayers or their anger averted by sacrificial offerings. It was worthy of note that in ancient Rome the women did not resort to the shrine of Juno, Venus, or even of Demeter, but to that of the chaste Diana, the one virgin goddess of classic mythology. The priest might by an incantation or prayer bring some solace to the woman anticipating with dread her labour with all its peril and suffering. If all was normal the help of the god would be acknowledged with a votive gift; but if disaster or death occurred it was attributed to the anger or curse of an unappeased deity. The priest played the part of physician, and they knew that in Egypt as early as B.C. 3500 there was a class of priest-physicians whose duties were mainly concerned with the bodily ailments of the suppliants and especially with those of pregnant women. The earliest compend of their art was to be found in the Hippocratic writings. This focussed the practice of midwifery at the time of Hippocrates (400 B.C.), and his teaching, crude and fallacious as much of it was, represented most of the obstetric art of nearly 2000 years. The study of anatomy at the beginning of the Christian era under the Ptolemies of Alexandria rectified many of the Hippocratic errors, and the influence of this knowledge was seen in the works of Soranus, Galen, Aretæus, and Moschion. But from the seventh to the sixteenth century obstetric art stood still, till in the latter century the school of Salerno inaugurated the teaching of anatomy, and the light shed its influence on the dark practice of obstetrics. Progress was at first slow, but by anatomists like Vesalius, Berengarius, Fallopius, and surgeons like Paré a scientific basis was laid. Further, while ordinary labour was still attended by women the surgeon was more and more frequently called to difficult cases. The seventeenth century was noted by the great development in practical midwifery rendered possible by the invention of forceps, though their use was not general till the early years of the next century.

In the eighteenth century they met with names of men whose contributions to midwifery would be difficult to over-estimate; in England Smellie, Hunter, and Denman; in France Levret and Baudelocque; and in Germany Roederer helped largely to the establishment of obstetrics as a science and art. There were three special epoch-making contributions during the closing century. In 1818 Naegelé published his work on the Mechanism of Labour which had been called the "Euclid of Obstetrics," and enabled the observer of a labour to become a scientific obstetrician and thus to raise himself above the level of the ordinary midwife. 30 years later another epoch was reached when Simpson discovered that anæsthesia could be used to soothe the suffering without interfering with the efficient progress of labour, and also enabled the obstetrician to apply all the resources of his skill on behalf of suffering motherhood. A third epoch was initiated by Lister when he gave the world the principles of antiseptic surgery. Though much had been done for their science and art, yet there were still problems to be solved. Among these were the true significance of menstruation and its relation to ovulation and conception; the function and destiny of the corpus luteum and that perennial subject the structure of the placenta; the true duration of pregnancy; the cause of labour; the nature of the process concerned in the involution of the uterus and the cause of eclampsia. In virtue of the labours of those before them they claimed that for every strictly obstetrical complication which could arise, with perhaps the exception of eclampsia, they had at their disposal a procedure with which they could meet it—that, in fact, there was scarcely a peril which could befall a woman in travail out of which they had not the means of rescuing her. This applied strictly to obstetrical complications and did not include accidental complications, as grave disorders of the heart, the lungs, and the kidneys. Yet in their land nearly 5000 women perished every year in the perils of childbed. Between the years of 1847 and 1856 the average annual death-rate from puerperal fever was 1·89 per 1000; during these years chloroform was coming into use and antiseptics had been scarcely thought of. Between 1875 and 1884 the mortality from the same cause rose to 2·28 per 1000 births. By this time anæsthetics were in wide use and antiseptics were taught and practised to a great extent. Between 1886 and 1895 the mortality had now risen to 2·46 per 1000 and anæsthetics and antiseptics had been almost universally practised. Attempts had been made to account for this great proportion of septic deaths in labour by the error of practice of ignorant midwives. But they were not more numerous and more densely ignorant now than they were 50 years ago. It was different with maternity hospital practice. In the early part of this century the hospital mortality was frightful, but now, as in 1896-97 at the Rotunda Hospital, it was reduced to 0·13 per cent. Why, then, were the results of private practice so far behind those obtained in hospitals such as the Rotunda, and becoming worse and worse in spite of accurate scientific knowledge, improvements in instrumental appliances, and increased practical skill? The explanation would be found in, first, the misuse of anæsthesia, and, second, in the ridiculous parody which in many practitioners' hands stood for the use of antiseptics. With the advent of anæsthesia interference in labour had become more frequent and because it involved no additional suffering operations were undertaken, when really unnecessary, on the demand of the patient or for the convenience of the practitioner. And so complications arose and the dangers of labour increased. Normal labour was a natural process which was best left to itself and the less the patient was disturbed with the paraphernalia of obstetrics before or after the better. But the moment they interfered it became a complex and dangerous process and it was simply because this was constantly ignored that the death-rate of childbed was what it was to-day. The fact must be recognised that the simplest obstetric operation demanded not one whit less of care as to antiseptic precautions than was required of one before opening the abdomen. A bruised or lacerated maternal canal was quite as susceptible to microbic attacks as the peritoneum and probably more so. The practical obstetrician must realise his responsibility that labour was a natural process which in the great majority of cases it was criminal to disturb. Every interference increased the inherent danger a hundredfold, and under this consciousness the obstetrician must bring with him to the lying-in room all that was possible of those principles of antiseptic surgery which had been at the bottom of the triumphs of modern gynæcology. Then they would not have long to wait for the lightening of the dark cloud which hung over them now.

Dr. BERRY HART read a paper on Extroversion of the Bladder. This condition and its allied lesions resulted from fissures occurring in the mesial line between the navel and perineal body. They varied in extent and depth and thus might only affect the skin, resulting in mere cutaneous cicatrices, or they might go deeper and expose the anterior surface of the bladder, or deeper still, and the urethra and posterior surface of the bladder would then be laid open. Similar lesions were the cause of epispadias and sub-symphyseal exstrophy, while the bones might be affected and split pelvis be present in some cases. They were all the outcome of developmental deficiencies and it was of consequence to trace their origin to very early fœtal life. The bladder did not arise from the allantois except at its very apex. It originated from a division of the caudal segment of the primitive gut into two parts by coronal folds; the anterior was the bladder and the posterior was the rectum. Dr. Hart discussed the questions of the tail-gut, entodermal cloaca and cloacal membrane, and especially the relations of the cloacal membrane to gastrulation. Extroversion of the bladder and allied conditions were due to a yielding or separation of the cloacal membrane; the immediate cause of this yielding was not yet known.

Dr. J. W. BALLANTYNE read a paper on Cleidotomy. This was the term applied to the division of the clavicle, and in all or nearly all its indications it was accessory to craniotomy or basilysis. Dr. Ballantyne related a case where after basilysis in a flat and small pelvis there was delay and difficulty owing to the arrest of the shoulders at the brim. One clavicle was cut through with a pair of long strong scissors, and this allowed the shoulder to fall in with consequent diminution of the circumference. The shoulders were then easily delivered by passing a blunt hook into the opposite axilla. Some difficulty was experienced with the passage of the child's hips through the brim of the pelvis. The diminution on the bis-acromial diameter would probably be about half an inch. Dr. H. R. Spencer first wrote about the division of the clavicle when it was necessary to diminish the width of the child's shoulders; he had found it very useful. Different obstetricians, as Phänomenoff, Knorr, Guérard, and others, had since written about this operation. The operation was easily performed by a pair of long straight strong scissors; they were passed up under cover of two fingers of the left hand and the bone with the skin covering it was easily snipped through. The two parts of the clavicle would be felt to over-ride at once if the section had been complete. There was really no danger of wounding the maternal parts, and even the subclavian vessels of the infant need not be injured if reasonable care be taken. On a dead infant Dr. Ballantyne measured the bis-acromial circumference and found it to be 27 centimetres, with the clavicles compacted on the chest it was 25 centimetres, with one clavicle divided 23 centimetres, and with both 22 centimetres. The indication for the operation was any disproportion between the size of the shoulders and the pelvic canal, and perhaps also to hasten labour in cases requiring urgent delivery.—Dr. MILNE MURRAY, Dr. J. FOULIS, Dr. HAULTAIN, and Dr. W. FORDYCE made remarks on the paper.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The second meeting of the session of this society was held on Nov. 21st, Mr. W. B. Holderness, J.P., the President, being in the chair.—The following gentlemen were elected members of the society:—Mr. F. Treves, surgeon extraordinary to Her Majesty the Queen, Mr. J. Harrison Scott, and Mr. S. Osborn; Mr. R. H. Paramore, house surgeon to the Windsor Royal Infirmary, was elected an honorary member.—Dr. A. J. Anderson showed the following patients:—1. A patient, aged 70 years, from whom he had Excised a third of an inch of the left Vas Deferens for retention of urine due to enlarged prostate. The use of the catheter was discontinued two days after the operation, though it had been necessary two or three times a day before, and the urine had since passed without the slightest trouble. 2. A man, aged 72 years, from whom he had removed a large Tumour of the Testis. The growth of the tumour was accompanied by a good deal of hectic fever which disappeared after the operation. The tumour was exhibited.—Dr. J. K. Watson showed the following case and specimen:—1. A case of Injury to the Elbow-joint. There was much limitation of flexion and extension, though pronation and supination were perfect. There was much pain due to involvement of the ulnar nerve in the callus. 2. A specimen of a Perforating Gastric Ulcer. The case occurred in a girl, aged 21 years, who had previously only complained of a few dyspeptic symptoms. Death occurred 27 hours after perforation.—Dr. C. R. Elgood showed a case of Ulceration of the Epiglottis presumed to be tuberculous.—Dr. E. B. Hulbert, by permission of Mr. J. R. Lunn, of St. Marylebone Infirmary, showed (1) a specimen of Sacculated Aneurysm of the Abdominal or Thoracic Aorta; (2) a Heart affected with Ulcerated Endocarditis (both the mitral and aortic valves were involved); and (3) several Drawings and Photographs of uncommon diseases, including Osteitis Deformans, Charcot's Disease, Tabetic Feet, Syringomyelia, Arthritis of the Temporo-Maxillary Articulation, and Tuberculous Disease of Various Joints.—Dr. W. F. Lloyd gave a demonstration upon Polarimetry. Having first pointed out the meaning of plane polarised light and demonstrated the movements supposed to take place in the ether by means of a pendulum he described the construction of a Nicol's prism and explained the rotation of the plane of polarisation. He then demonstrated by means of models the structure which the carbon molecule was supposed to have when associated with the power of rotating the plane of polarisation. Having pointed out the importance of the polariscope in the detection of β oxybutyric acid he described and exhibited a polarimeter, demonstrating the rotation of the plane of polarisation in diabetic urine.—Dr. A. J. Anderson read a paper on Drain-Poisoning in Private Practice. After alluding to Mr. Pridgin Teale's remarks on this subject as early as 1878 he said that in the matter of sanitation we were still far behind other countries, especially America. He next referred to the evils resulting from *jerry-building*, instancing cases of bronchitis, pneumonia, whooping-cough, and rheumatic fever. As examples of well-known diseases caused by sewage emanations, diarrhœa, gastro-intestinal disturbance, and certain forms of sore-throat simulating diphtheria were mentioned, and he thought that cholera, enteric fever, erysipelas, pneumonia, puerperal fever, and diphtheria had a heavier incidence on persons exposed to their baneful influences. He laid great stress on the importance of self-education in the matter of drainage and the absolute necessity of a personal supervision of the work of plumbers, builders, and even architects. He finally instanced several cases which had come under his notice where some insidious disease had been clearly traced to drain-poisoning and called attention to the lowered state of vitality, entailing neuralgia and other minor ailments observed in those who were more slowly poisoned by sewer-gas.—An interesting discussion followed, in which Dr. E. Casey, Mr. J. Startin, Mr. J. H. Tomlinson, Mr. H. E. B. Porter, Dr. Hulbert, and Dr. G. E. Hale took part.

Ipswich Clinical Society.—A meeting of this society was held on Nov. 15th, Mr. C. K. Moseley being in the chair.—Dr. B W Brogden showed a case of Hodgkin's Disease The patient was a girl, aged 19 years. The glandular swellings affected both axillæ and both sides of the neck, chiefly in the posterior triangles. Some were of the size of large plums. The parotid, sublingual, and submaxillary glands were unaffected; there was no pain or tenderness or sign of any breaking-down process. There was no abnormality in the abdomen or thorax. The girl was markedly anæmic, the blood showing considerable diminution of the red corpuscles, and she suffered from amenorrhœa. Iron, arsenic, and iodide had so far caused no improvement Dr. Brogden mentioned two other cases, both ending fatally.—Mr. J. R. Staddon and Dr. H. H. Brown also mentioned cases.—Dr. Brogden showed an old man from whom he had successfully excised the upper jaw for a large Epitheliomatous Growth affecting the Antrum.—Mr. Wynne Davies showed: (1) A woman, aged 50 years, who had quite recently cut a Lower Canine and Two Lower Incisor Teeth; and (2) a middle aged woman with a Chronic Ulceration at the Angle of the Mouth, probably a rodent ulcer.—Mr. Sinclair showed: (1) A case of Chronic Irido-cyclitis in a young girl without any history of a constitutional cause; (2) a case of Chronic Interstitial Keratitis in one eye of a healthy young woman with complete absence of congestion; and (3) a case of Vascular Pannus without Granular Lids under treatment with infusion of jequirity.—Mr. Moseley read notes of a case of Acute Peritonitis. A man, aged 32 years, was attacked after a hearty meal with abdominal pain and sickness. He vomited two or three times and had several loose motions. This went on during the two following days, and he was first seen on the fourth day, when he said that he had one of his old "bilious attacks, but that it was lasting longer than usual." He was very ill. His tongue was dry and his pulse was uncountable. His temperature was 100°F His abdomen was retracted all over and was tender on deep pressure. He was given a quarter of a grain of morphia. Five hours later the pulse had improved, but his condition was otherwise unaltered. Later in the evening he vomited once and hiccough came on, and the lower part of the abdomen was found to be tympanitic. At midnight Mr. Moseley performed laparotomy. Foul gas and some thin pus escaped from the peritoneal cavity; the intestines were everywhere moderately distended; the appendix was soft and swollen and contained a hard mass within it. It was removed. The intestine in its neighbourhood was acutely inflamed and it showed numerous patches of gangrene. The patient died five hours after the operation.—Mr. Moseley, Dr. H. H. Brown, and Mr. J. F. C. Hossack commented on the case.

Chelsea Clinical Society. — An ordinary meeting of this society was held on Nov. 20th, the President, Dr. W. Ewart, being in the chair. — Mr. J. Foster Palmer showed an Unusual Organism, believed to belong to the class of Myriapodes, which had been expelled from the urethra of a male patient.—Mr. E. D. Vinrace showed a Foreign Body also expelled from the Urethra of a male patient. The history of the case was that the patient, who was suffering from symptoms of vesical irritation, had passed for himself a bougie made from an ordinary candle. The foreign body in question was composed of phosphatic material embedded in what appeared to be paraffin wax.—Mr. Noble Smith read a paper on the Conservative Treatment of Tuberculous Disease of the Joints. He described the principles of efficient local fixation of the diseased parts as carried out at the City Orthopædic Hospital. He advocated operation upon the bones in the neighbourhood of diseased joints in the early stages of disease as a means of rendering excision unnecessary, and he expressed doubts as to the necessity of amputation in almost every case of tuberculous joint disease. Mr. Smith exhibited two patients. One was a child, aged two and a half years, in whom extensive disease of the tarsus had existed for which amputation had been recommended while efficient fixation had been neglected. Removal of some diseased pieces of bone, fixation with a simple iron splint, and appropriate and persistent full feeding had been carried out for some months. The sinuses had healed up and the general condition of the child had greatly improved. There was free movement of the ankle-joint and there could now be no question of amputation. The child had also suffered from diseased bone in the face and left hand, but these places also were healing, or had healed up, and the child was becoming quite robust. She seemed likely to be completely cured. The second patient exhibited was an adult male who was suffering from caries in the mid-dorsal region. The disease seemed to have been arrested, although at one time, prior to complete fixation of the spine and good feeding, the disease had been so advanced that the patient had upon two occasions coughed up pieces of bone, evidently from the spine. Mr. Smith urged that complete fixation of joints, removal of diseased bone without the excision of joints and in the majority of cases without even opening joints, together with full and nutritious feeding, constituted the most successful line of treatment.—A discussion followed in which the President, Dr C. A. Morris, Dr. Vincent Dickinson, Dr C. J Harrison, Mr. Vinrace, and Mr. R Nitch Smith took part.

South-West London Medical Society.—A meeting of this society was held on Nov. 14th, Dr. Gilbert Richardson being in the chair.—Dr. S. H. Habershon read a paper on the Diagnosis of Gastric Ulcer, with some remarks on its Treatment and Prognosis. He opened the subject with a short description of the incidence of the disease at various ages, showing by tables the absolute liability of each period of life. He emphasised the fact that some special cause for gastric hæmorrhage, as well as a special liability to perforating gastric ulcer, existed in young females. In males the liability to the disease gradually rose from infancy to old age. Enumerating the difficulties of diagnosis Dr. Habershon divided the cases into four classes: 1. Cases simulating acute dyspepsia or acute gastric ulcer in which the typical symptoms were wanting and the true nature of the case was suddenly revealed by gastric hæmorrhage or perforation. There was a class also in which the disease was entirely latent and the first important symptom of which was sudden perforation. 2. Anæmic gastralgic cases in which pain occurred not only after food but after any exertion or fatigue. 3 Neurotic cases of irritable stomach, where there was often an exaggerated account of pain, sometimes accompanied with incessant vomiting. 4. Cases of gastric ulcer in the pyloric region, the symptoms of which were always anomalous and where pain occurred at irregular intervals, which was sometimes relieved by food. In these cases vomiting was not always present and hæmatemesis was not a constant symptom. Gastric dilatation was almost always present in the late stages of the disease. Dr. Habershon emphasised the importance and difficulty of diagnosis in these cases and made some remarks upon the methods of examination of the stomach in neurotic cases, laying stress upon the help in mapping out the outlines of a dilated stomach given by the bell sound and the conduction of the second cardiac sound. Dr. Habershon closed with some remarks on treatment, medical and surgical, and upon the indications which aided in making a prognosis.

BOURNEMOUTH MEDICAL SOCIETY.—A meeting of this society was held on Nov. 14th, Dr. Arthur Ransome, F.R.S., the President, being in the chair. There was a large attendance of members.—The resident medical officers of the National Sanatorium for Consumption and Diseases of the Chest, of the Royal Victoria Hospital, and of the Royal Boscombe and West Hants Hospital were elected honorary members during their term of office, and seven new ordinary members were elected.—The President read a paper on Aseptic or Anti-Microbic Medicine. He recalled the fact how widely spread was the anti-microbic principle in medical practice and gave instances of the means adopted by nature to prevent the action of microbes. He thought that the aseptic or anti-microbic treatment might be arranged under the following heads, which were considered in detail: (1) those which were intended to keep the organisms at bay, to prevent them from approaching a wounded surface or from entering any of the portals of the body; (2) those which were designed to meet and kill the organisms or to destroy their virulence either on their approach or after they had affected an entrance; and (3) those which were concerned with strengthening the natural defences of the body against the inroads of pathogenic microbes.

CLINICAL SOCIETY OF MANCHESTER.—An ordinary meeting of this society was held on Nov 20th, Mr. F. A. Southam, the President, being in the chair.—Dr. A. T. Wilkinson showed some cases of Abdominal Affections.—Mr. E. Stanmore Bishop showed a large Fibro-myomatous Uterus.—Mr. Francis Riley read the notes on a case of Cerebro Spinal Meningitis and showed the patient.—Mr. J. E. Platt presented a case in which Popliteal Aneurysm had been successfully treated by ligation of the Femoral Artery.—Dr. E. S. Yonge gave a short demonstration on some of the more recent Devices for examining the Larynx in Children.

ROYAL METEOROLOGICAL SOCIETY.—The opening meeting of this society for the present session was held on Nov. 21st at the Institution of Civil Engineers, Great George-street, Westminster, Dr. C. Theodore Williams, the President, being in the chair. Among other papers read was one by Mr. W. H. Dines on the Weekly Death-rate and Temperature Curves, 1890–99. He exhibited diagrams showing the death-rate of the 33 great towns of England and also curves of the temperature at Greenwich. Mr. Dines was of opinion that from the health point of view the English climate was one of the best in the world, and this was proved by the relatively low rate shown in these curves. A pleasanter climate might well be found, but the majority of health resorts to which Englishmen went in the winter had a higher death-rate than London had at the same season and a far higher death-rate than any of the country districts of the British Isles.

Reviews and Notices of Books.

Malaria according to the New Researches. By Professor ANGELO CELLI, Director of the Institute of Hygiene, University of Rome. Translated from the second Italian edition by JOHN JOSEPH EYRE, M.R.C.P., L.R.C.S. Irel., D.P.H. Camb. With an Introduction by Dr. PATRICK MANSON, Medical Adviser to the Colonial Office. With Maps and Illustrations. London, New York, and Bombay: Longmans, Green, and Co. 1900. Price 10*s.* 6*d.*

THE history of all the recent researches in connexion with malaria—from the original discovery of the malarial blood parasite by Laveran in 1880 up to the time of the latest investigations establishing the mosquito-malarial theory—makes up one of the most original and interesting chapters in the record of modern scientific investigation. It has revolutionised our views in regard to malaria. Researches which have been worked out with so much patience and subtle skill, have established a causal connexion between malarial disease in the human being and the anopheles mosquito not only as a carrier but as an intermediary definitive host of the malarial parasite during an important phase of its life-history. If the correctness of this view be admitted it seems to follow that the mosquito must be the only means by which malaria is transmitted. The germs of malaria external to man do not live in the soil, but in the body of the mosquito. The story is so curious and interesting that it reads as if it might be a product of the scientific imagination. But it is nothing of the kind; the mosquito-malarial theory has been worked out by an inductive method of reasoning and on the lines of scientific observation and experiment. That the theory may be still incomplete in some respects is only tantamount to saying that progress in all inquiries of a complex nature must be more or less slow and gradual if such inquiries are to include all the facts and phenomena and to account for or to explain such of them as may be really, or only seemingly, in conflict with the theory. The subject has been, and is still being, keenly cultivated, and all things considered it is remarkable how much has been already accomplished. Important additions of a confirmative kind are so frequently being added to our stock of knowledge that even the volume under review does not contain them all.

The causes and consequences of malaria more or less concern everybody, especially the people of the British Empire, who are the most cosmopolitan people in the world. So much has been written regarding the results of the latest investigations that a knowledge of them has become, as it were, common property. Our readers, of course, are acquainted generally with the main facts, and such of them as are more directly concerned with the study or treatment of malarial diseases have kept themselves *au courant* with the progress of our knowledge in this direction. The subject is not merely a matter of scientific interest to members of the medical profession and to the naturalist and to the microscopist. It has a far-reaching practical side to it. The confirmation of the mosquito-malarial theory has not only demonstrated the importance of using quinine for the cure of malaria-infected subjects, but it has already led to the employment of new methods of prophylaxis as regards the genus of mosquito concerned—such as the use of larvicidal agents in pools and puddles, to prevent mosquitoes from breeding in them, and other plans—in addition to those designed for the protection of man against being bitten by them.

All this, with much besides, has been set forth in a very lucid and comprehensive way in Professor Celli's work which has the merit, moreover, of being written in a scientific spirit. There have been a large number of labourers in this field of scientific investigation. The Italian school has always occupied a conspicuous position in regard to the study of malaria and its members have maintained that position, as Dr. Manson tells us, by being the first to confirm Major Ross's brilliant investigations, and by throwing themselves energetically into the hygienic measures which these researches plainly indicated. The name of Professor Celli has long been honourably associated with a number of other well-known Italian authorities whose names occupy a distinguished position in connexion with the scientific study of malaria and its prevention. Professor Celli now appears as the author of an excellent piece of scientific literary work based upon and setting forth the latest researches and the lessons which they inculcate, and suggesting the best methods of applying prophylaxis.

The work is divided into two parts. The first deals with epidemiology, the second with prophylaxis. It is illustrated by many excellent plates, maps, and plans and is furnished with an exhaustive bibliography of Roman malaria. In Part I. the etiology, the sources of malarial infection, the life of the malarial germs in the environment—in short, the whole life cycle and natural history of the malarial parasite,—the vehicles of malarial infection, and the causes of predisposition or of immunity towards malaria, are well worked out. In Part II. the means to be directed against the infective cause and against the predisposing causes of paludism are discussed in a sound and practical way. How clear Professor Celli can be here is well shown by the translation of his article in the *Policlinico*, which we publish on page 1603.

Die Krankheiten der Warmen Lander. (*The Diseases of Warm Countries*) By Dr. B. SCHEUBE Second revised edition. Jena: G Fischer. 1900. Super Royal 8vo. Pp. 662. Five charts, seven plates, and 32 illustrations in the text. Price 15 marks.

A GLANCE at the work that has been done in the matter of tropical medicine during the four years which have elapsed between the publication of the first and second editions of Dr. Scheube's book shows to what a remarkable degree interest has been roused of late in this department of science. Three journals dealing with the hygiene and diseases of warm countries have appeared, schools of tropical medicine have been established, conferences have been held, and commissions have been appointed to study particular diseases. From another point of view, however, the activity recently displayed by German investigators in this field forms a significant commentary on the ardour with which their country is prosecuting colonial enterprises, and tells plainly of the toll which must be paid in sickness and death by every country which aspires to a "Weltpolitik." Whatever complications may be introduced into the world of commerce and politics by German competition we cannot but welcome German cooperation in the work of combating tropical diseases, especially when it takes the form of such a volume as the one before us. The book is rendered remarkable by the grasp of his subject displayed by the author, by his extensive knowledge of its literature, and by the lucidity of his descriptions. Not less noteworthy is the sense of proportion which prevents him from devoting an undue amount of space to the subjects with which his name is specially associated—a very unusual trait in the writer of a handbook. The author divides his subject matter conveniently into six sections: 1 General infectious diseases—plague, malaria, leprosy. 2 Intoxications—pellagra, lathyrismus, snake-poisoning. 3 Affections due to animal parasites. 4. Diseases of organs—a somewhat vague term which includes not only tropical dysentery and hepatic abscess, but also the sleeping sickness of negroes, amok-running, and lata. 5 External diseases, such as prickly heat, ainhum, mal de Pinto. 6. "Cosmopolitan" diseases.

The first section is, of course, the most important It begins with a succinct account of the bubonic, septicæmic, and pneumonic types of the plague, and discusses in a few lines the intestinal form, which the author considers a distinct variety. As regards the so-called pestis minor he is inclined to disagree with Mr. Cantlie and to look upon it as a form of climatic bubo and as having nothing to do with the plague. Until the bacteriology of climatic bubo has been worked out, however, it is impossible to speak positively on the subject.

The diagnosis between dengue and influenza, particularly in some epidemics of the latter, is scarcely so easy as the author suggests. The pains in the limbs, the principal characteristic of the former, are, he says, absent from the latter, but a wonderfully close imitation of them is sometimes provided. In the prophylaxis of malaria the author rightly lays stress on the observance of those precautions in the matter of diet, clothing, and architecture which experience has shown to be of value even though they may prove to have been based on an erroneous theory of the etiology of the disease. In the attention paid to the mosquito as an etiological factor these precautions may perhaps be neglected. Into the question of diet Dr. Scheube enters at some length. He commends the practice which obtains in the Dutch East Indies of lunching in native style—i.e., largely on rice and curry—and dining as a European. Whatever the theoretical merits of this plan may be, we doubt if its practical application in the mid-day "rice-table" of the Dutch hotels in Java is an example to be followed except by the fortunate possessors of a Dutch digestion.

The predisposing cause of blackwater fever the author considers to be chronic malaria; the exciting cause may be a fresh attack of fever sufficiently severe alone or when accompanied by the administration of quinine to break down the weakened blood corpuscles. In a suitable case quinine alone may, if given in doses large enough, have the same effect. Unless there be a special idiosyncrasy towards the drug (cases have been observed in which small doses in healthy persons invariably caused hæmaturia) he does not consider that the hæmaturia is set up apart from malaria As regards frambœsia Dr. Scheube treats Mr. Hutchinson's suggestion of the relationship between yaws and syphilis somewhat cavalierly. "To confound frambœsia with ...... syphilis," he says, "is scarcely possible," on the ground that the two diseases can co-exist, and that syphilitic persons in all stages of their complaint can be affected with frambœsia, and *vice versâ* The etiology of amok-running is still quite obscure, while to regard lata, which Van Brero defines as "an induced imitative impulsive myospasia," as a neurosis which renders the patient exceedingly susceptible to suggestion seems to be as far as we can go at present in the direction of etiology.

A curious feature of Dr. Scheube's book is that he has excluded cholera from consideration altogether, on the grounds that it is a disease of tropical countries, not of "warm lands," and that it is described in every text-book and handbook of special pathology and therapeutics. After admiring the masterly way in which most of the tropical diseases have been discussed, the first of these *two* reasons sounds rather quaint, while a glance at the copious literature appended by the author to the chapters on these diseases makes us wonder why in the second reason so invidious a distinction should be made in the case of cholera. Some useful charts will be found at the end of the book which give the geographical distribution of malaria and blackwater fever, of beri-beri, leprosy, filariasis and ankylostomiasis, and some exquisite photographs of leprosy, elephantiasis, and gundu.

Dr Scheube's work is not only an important addition to the literature of tropical diseases but will be found very useful both as a text-book and as a book of reference. It is one of the most satisfactory books that we have read for a long time.

The Climatic Conditions necessary for the Propagation and Spread of Plague. By BALDWIN LATHAM, M. Inst. C.E., M. Inst. M.E., &c. Reprint from the *Quarterly Journal of the Royal Meteorological Society*, Vol. XXVI., No 113, January, 1900. Edinburgh: Printed by R. and R. Clark, Limited. Pp. 57. Illustrated.

THE object of this paper is to find a direct relationship between emanations from the soil and the incidence of plague. By means of a most painstaking and instructive series of charts the author proceeds to prove that the periodicity observable in the mortality from plague in Bombay and other populous centres presents a most striking similarity to the periodicity manifested by soil emanations at corresponding periods. When dealing with facts the author is on safe ground, especially when these facts concern meteorological and statistical questions. The deductions, however, which he draws show a want of appreciation of the laws which govern bacterial life and bacterial distribution. He believes, for instance, that ponderable organic units in the form of plague and tubercle bacilli, as well as the specific germs of malaria and certain lung diseases, can be carried in the gaseous emanations from the soil and thus may infect both man and animals. The climatic conditions which control vapour tensions at the surface of the soil—and consequently the upward or downward direction of the gaseous current—must clearly influence in some degree the health of the human organism and its powers of resistance, and possibly that of the intermediate hosts which participate in the distribution, but it is impossible to believe that the periodicity of plague mortality is directly due to a similar periodicity in the upward current of soil vapours containing the bacillus pestis.

Mycosis Fungoides. By JAMES GALLOWAY, M.D. Aberd., and J. M. H. MACLEOD, M D. Aberd. London: H. K Lewis. 1900 Pp. 26. Two Coloured Microscopic Plates.

THIS is a reprint from the *British Journal of Dermatology*. It is a clinical and pathological study of three cases of this rare, interesting, and generally dangerous disease. In two of the cases the patients are still living; the third patient is dead. Examination of the blood showed that in Case 1 it was fairly normal, there being no leucocytosis and no esinophilia as some authors have described. Injection of Coley's fluid was tried in one case with some amelioration of symptoms, there being less pruritus and a diminution of infiltration. One case began with intense pruritus and redness, another with the formation of a small red patch without any symptoms, but the patches increased in number and size rapidly. The third case was under the care of Dr. Stephen Mackenzie. The eruption was at first dry, scaly, and pigmented, followed by slightly raised infiltrations, which ulcerated. No visceral disease was found at the post-mortem examination. Careful histological examination led the authors to the conclusion that the infiltration was chiefly due to connective tissue cell proliferation, first in the upper third of the corium and later spreading downwards, and that the process was that of an infective granuloma. In the epidermis in the early stage there was proliferation of the prickle-cell layer and in the later absorption of it from the upward pressure of the granuloma. In the bacteriological examination the authors were aided by Dr. J. W. H. Eyre. They found organisms, including a variant of Friedländer's bacillus, but their general conclusions were that all the organisms present were accidental and not pathogenic.

The whole essay represents much careful and laborious work, and is therefore a valuable contribution, although the authors, like their predecessors, have not been able to solve the pathological problem offered by this terrible disease.

House Drainage and Sanitary Fitments. By GERARD J. G. JENSEN, C.E. London: The Sanitary Publishing Co. 1900. Crown 8vo, pp. 257. Price 5*s.* net.

ATTENTION to details is generally found to be the secret of success in every undertaking. Possibly there are few subjects where neglect of apparent trifles is so fraught with danger to the community as in work connected with the sanitary surroundings of our dwellings. Mr. Jensen's little book is devoted to detail, and though he tells us little or nothing that is new, still it may be regarded as a valuable addition to sanitary literature. Technicalities being as far as possible avoided, it is rendered as acceptable to the layman as is compatible with the subject. The book is really a compendium or commentary upon the various materials and fittings commonly used in sanitary work and points out their uses, their several defects or advantages, and explains why the author arrives at his conclusions. To the student or those engaged in work of this nature the book will be found exceptionally handy for reference, it being well supplied with simple tables giving various formulæ which are constantly required but too often neglected. There are plenty of capital illustrations and plans and their value is enhanced by a good index.

It is a pity that Mr. Jensen has admitted, although with evident reluctance, the combined slop-hopper and housemaid's sink among his illustrations, unless for the purpose of condemning it. If the use of a slop-hopper is unavoidable it should be fixed in a separate apartment away from that in which drinking-water is drawn. Also, with regard to his condemnation of waste water-closets we would go further and say that such a disgusting arrangement should be abolished altogether. In any situation where they might be considered necessary a dry earth catch (not a pail) could be used with advantage.

Bacteria, especially as they are related to the Economy of Nature, to Industrial Processes, and to the Public Health. By GEORGE NEWMAN, M.D., F R S. Edin., D.P H. Cantab Second Edition. London: John Murray. 1900. Pp 397. Price 6*s.*

BACTERIOLOGY grows apace and it is therefore not surprising that original editions of text-books upon the subject have soon to undergo revision and expansion. The first edition of the book before us was issued in 1899 and was reviewed in THE LANCET of Nov. 25th, 1899, p. 1448. We commended it and regarded Dr. Newman's contribution as a valuable addition to the "Progressive Science Series" although we joined issue with him on certain points. In the present edition he has omitted some of the statements upon which we animadverted, while other statements he has modified in accordance with our criticisms. The present edition is an advance on the first edition chiefly in that it contains new chapters on tropical diseases, the bacterial treatment of sewage, and the industrial application of bacteriology. These new chapters are very well written and are fully in accordance with the results of modern inquiry. He describes, for instance, the recent experiments by Dr. Frank Clowes on the efficiency of coke-bed filters, a work which is undertaken, of course, on behalf of the London County Council. Again, he refers to the interesting observations of Dr. A. C. Houston on the bacteriological aspects of this method. The deposit which accumulates on the coke fragments used in the beds at Barking and Crossness proved to contain 1,800,000 bacteria per gramme. Since this quantity of typhoid bacilli, according to Dr. Houston, weighs only 0 0000147 gramme, it is evident that the numbers of living bacteria do not in themselves account in any way for the deposit. Dr. Clowes found that the deposit consisted largely of woody matters. The chapter on Tropical Diseases is quite fresh and is interleaved with microscopical illustrations of, amongst others, the bacillus of plague and the bacillus of leprosy. A brief account of the rôle played by the mosquito in the propagation of malaria occurs as a reference to recent investigation. The chapter on Disinfection is instructive and though exhaustive enough in a popular work it might usefully have been made to include some of the newer chemical substances now contained in the category of disinfectants and antiseptics On page 375 it is stated that "potassium permanganate is of course the chief substance in Condy's fluid." We believe that the manufacturers have denied this again and again, and it is fairly common knowledge now that Condy's green fluid is *sodium* manganate, while the red fluid is *sodium* permanganate It is not easy to write correctly upon bacteriology in popular language, but we think that Dr. Newman has succeeded very well in presenting a clear and intelligent account of the present position of the science. If it had been otherwise there would have been no call for a second edition.

Transactions of the Society of Anæsthetists. Vol. ii, 1899. London: The Medical Publishing Company. Pp. 231. Illustrated.

THE second published volume of these Transactions contains 11 papers or contributions to discussions. While points of interest occur in all of these some lack the originality which usually reveals itself in transactions of a learned society. If transactions are worth publishing they should contain no papers which are without some claim to originality. Professor Ramsay, who, by the way, is misnamed in the contents, deals with Pure Anæsthetics, and although his views concerning the best ways of preventing decomposition in chloroform are not accepted by all practical chemists his paper will be read with interest. The trend of expert opinion seems at present towards believing that the impurities in chloroform are responsible less for the acute than for the remote dangers incident to that anæsthetic. The discussion upon the question, "What anæsthetic should be selected in various conditions?" is one of great interest It is perhaps to be regretted that there were not more speakers who could find a use for all anæsthetics, each in its particular and appropriate place. The mere personal predilection is generally of less importance to the casual reader than the thought out arguments of men, which serve to guide him in difficult cases Dr. H G. Turney's paper on Post-Anæsthetic Paralysis is extremely good. Although much attention has been paid to this subject abroad, notably in Germany and in France, very little material of value has appeared in this country The addition of an index is distinctly an improvement to the present volume. No one who devotes himself to anæsthetics can afford to ignore the Society of Anæsthetists or its Transactions.

LIBRARY TABLE

An Outline Sketch: Psychology for Beginners. By HIRAM M STANLEY. Chicago The Open Court Publishing Company; London Agents. Kegan Paul, Trench, Trübner, and Co 1899. Small demy 8vo Pp. 44. Price 2s—This little book appears admirably to fulfil the author's intention of an introduction to psychology. It is written in a clear and interesting style and has practical exercises introduced into the text which will be useful both to teacher and to pupil. It may be commended to the notice of any beginner in the study of the elements of psychology, although it is in no sense a manual on the subject, and only gives the rudiments which should first be thoroughly grasped if a student is to obtain a lucid insight into this difficult and fascinating subject

The Insane in Private Dwellings and Licensed Houses. By J. F. SUTHERLAND, M.D, F.R.S Edin. Edinburgh: E. and S. Livingstone. 1897. Demy 8vo. Pp. 60 Price 1s.—Dr. Sutherland has produced a very instructive brochure on the advantages of the boarding-out system as it is carried out in Scotland, where it has been in use for 40 years, greatly to the advantage of the insane, to say nothing of a vast financial saving. The system has not apparently commended itself so highly to the authorities in England, where only 6 per cent. are boarded out as against 23 per cent in Scotland. It would seem to us that this method of treatment might be made more use of, at all events as an auxiliary measure for relieving the overcrowded asylums of some of their harmless chronic patients, whose removal would make room for more acute cases which should be admitted to asylum treatment without the delay which so frequently occurs under existing circumstances. The whole subject is one of great importance and all guardians of the poor and others concerned in the accommodation and treatment of lunatics should make themselves acquainted with the contents of this book Dr. Sutherland lays stress on the fact that since 1857, with an average of 2000 pauper insane in private dwellings, only one grave injury has taken place—a result which certainly compares favourably with the results obtained in asylums. The author's position as Deputy Commissioner in Lunacy for Scotland has given him ample opportunities of forming an authoritative opinion on the subject, and his remarks on central and local supervision and other details in the working of the scheme deserve careful attention. Dr. Sutherland estimates that a judicious extension of this system in England would result in an annual saving of £200,000. He thinks that instead of 5000 something like 17,000 patients might be provided for in this way.

Local Government Law and Legislation, 1899 By W. H. DUMSDAY. London: Hadden, Best, and Co. 1899. Demy 8vo Pp 279.—To all whom these Acts of Parliament concern the above volume, which is well arranged and well indexed, should prove of great value. The book is divided into four parts: Part I. recites the Public General Acts of 1899 with a few explanatory notes which might in some cases have been enlarged with advantage. Part II. consists of a Digest of Cases in the Courts alphabetically arranged. Part III gives a list of Miscellaneous Orders and Circulars for the year ended Sept. 30th, 1899, with remarks on the same Part IV. is a table of Public Bills in Parliament affecting local authorities which did not become law. The work is designedly a supplement to other text-books and should find a place on the shelves of the busy men who are obliged to keep themselves well informed on the current changes in legislation, as it will obviate the necessity of searching all the original digests and reports and therefore will prove a great saving of time and labour

The Pathological Statistics of Insanity. By FRANCIS O. SIMPSON, L R C P Lond., M R C S Eng London: Baillière, Tindall, and Cox. 1900 Royal 8vo. Pp 140. Price 10s. 6d. net—As its title implies this work consists largely of tables of statistics and the author is to be congratulated on the admirable manner in which he has dealt with the facts at his disposal The system on which the observations have been made is that suggested by Mr. W. Bevan Lewis and is most exhaustive. Pages 1 to 48 give Mr. Simpson's conclusions drawn from the consideration of an immense number of post-mortem records made in the West Riding Lunatic Asylum. The suggestion which the author makes that those interested in insanity should pursue their investigations on somewhat similar lines is worthy of careful attention as it is only by the comparison of a very large number of such observations that any results of real value are likely to be obtained Pp 43 to 131 contain a series of tables giving minute measurements of the cranium and brain in different classes of lunatics, with percentages of the abnormal conditions which are found in them, and should be of great use to all medical men interested in lunacy, more especially to those who have opportunities of making necropsies. In the section devoted to General Paralysis the author makes some interesting remarks on the rôle of syphilis as a factor in the causation of this disease, and adduces arguments in support of his contention that its influence has been greatly over-estimated. He says that "in only two males out of 95 paretics examined was any trace of exudative syphilitic process discovered, the lesion in each case being a gumma." It appears that general paralysis is much more prevalent in the north than in the south of England and that the type of the disease is more acute, cases rarely lasting for two years and frequently only for six months. Mr. Simpson does not advance any theory to explain this condition, but states that in his opinion alcoholic and sexual excesses and gonorrhœa are the most important etiological factors. The notes on the Breaking Strain of the Ribs are instructive, confirming Meyer's remarks that there is a tendency to increased fragility in the insane but not in paralytics. Induration of the white substance of the brain is, according to Mr. Simpson, of very rare occurrence and is neither pathognomonic nor pathogenetic of any form of epileptic insanity.

Writ in Barracks. By EDGAR WALLACE. London: Methuen. 1900. Pp. 121. Price 3s.—Mr. Wallace dedicates his little book to "the rank and file of the Army Medical Corps, amongst whom I spent six happy years of my life." Comparison with Kipling is inevitable, but we maintain that Mr. Wallace has no reason to shirk comparisons. His ballads deal mainly with South Africa and being in the Royal Army Medical Corps he naturally saw a good deal of the less attractive side of war, a note which is struck in the first ballad. Most of the others are good and one—"The Prayer"—is very good.

The Tale of a Field Hospital. By FREDERICK TREVES, F.R.C.S. Eng. London: Cassell and Co. Pp. 109. Price 6s.—This little book, beautifully got up in all the glory of morocco binding, uncut edges, and rubricated headlines and initials, sets forth in Mr. Treves's breezy style the pathos, the heroism, and the sorrows of war. The field hospital was No. 4 Stationary Hospital, so called, we presume, on the *lucus a non lucendo* principle, because it accompanied the Headquarters Staff of the Ladysmith relief column. Some of the matter has previously appeared in the pages of the *British Medical Journal*, but the book as a whole is simply an amplified record of notes taken on the spot. A perusal of its pages will serve only to increase our admiration for the grit of the British army from the highest to the lowest, but we may be pardoned for saying that the most interesting deed of heroism to ourselves is the account in Chapter xxix. of how Major Babtie won the Victoria Cross. The book is well illustrated with reproductions from photographs, and among all the pain and sorrow of the recital the photograph of "Hairy Mary" is enough to bring a smile to the most dolorous countenance. She looks exactly like a mammoth in the rough.

DISPOSAL OF AMPUTATED LIMBS.—At the meeting of the Cardiff Board of Guardians held on Nov. 20th the subject of the disposal of the amputated limbs of pauper patients was again discussed. It was stated that several of the limbs had been buried in the workhouse grounds, others had been interred with the bodies of paupers, and some had been sent to the pathological department of University College, Cardiff. One of the guardians said that a Protestant man complained bitterly on discovering that his amputated arm had been buried with the remains of a young Roman Catholic woman. After a long discussion it was decided that the patients should in future be consulted in the matter.

# Analytical Records
FROM
THE LANCET LABORATORY.

STRENBO.

(THE STRENBO CO., 64, CORPORATION-STREET, MANCHESTER.)

THE proximate analysis of this extract was as follows: moisture, 28·81 per cent.; ash, 17·44 per cent.; organic matters, chiefly proteids, 53·75 per cent. The total nitrogen was 8·04 per cent. According to the precipitate obtained on adding saturated zinc sulphate the albumose amounted to 10·12 per cent., while the peptones shown by the coagulation produced on adding bromine water amounted to 3·46 per cent. Considering these results with the fact that only 11·87 per cent. of the organic matters proved to be soluble in alcohol it is pretty clear that "strenbo" contains something more than the mere stimulating constituents of meat. Indeed, the view we take of these results is that this preparation is just as acceptable for its real nutritive value as for its stimulating properties. It contains a small amount of unaltered albumin (0·17 per cent.) and the insoluble proteids amounted to 1·30 per cent. The composition of this preparation is based evidently on the knowledge that ordinary beef-tea is little else than a stimulating fluid, for "strenbo," though it possesses stimulating properties, possesses, too, what is more important, real nutritive properties.

KOLE-SPAR.

(UNIQUE TRADING CO., WARWICK-STREET, ROTHERHAM.)

"Kole-Spar" is described as "the world-renowned coal-saver and consumes all the vitality there is in coal." One package costing 6*d.* saves, it is said, one quarter of a ton of coal. Our analysis disclosed the black glistening mixture to be carbon, common salt, and a little sulphur. The common salt amounted to nearly 85 per cent. In view of this analysis the following statements may be easily accepted: "Kole Spar can be handled by a child with impunity. It can do no harm to persons or grates and furnaces." In view of this analysis also the following claims may well be doubted: "Kole Spar destroys coal gas ...... prevents soot and cinders ...... prevents smoke ...... will make a poor quality of coal do the service of the first quality." All we can say is that these latter claims do not coincide with our experience, and that, if they did we should be inclined to think that common salt would be just as good as, while it certainly is much cheaper than, "Kole Spar." The preparation is decidedly novel; we have never heard of it before, but the current high price of coal probably accounts for its introduction.

LIQUID SOMATOSE.

(THE BRITISH SOMATOSE CO., 165, QUEEN VICTORIA-STREET, LONDON, E.C.)

Compared with somatose powder an increased palatability and an easier form for administration are the chief claims made in regard to this preparation. We have reported previously upon somatose powder which, for all practical purposes may be said to contain as its chief constituent albumose. This is evident from the fact that the proteids present are practically thrown entirely out of solution on the addition of a saturated solution of sulphate of zinc. Liquid somatose is a brown fluid with a pleasant meaty flavour which may be referred to the addition of a small quantity of meat extract. Liquid somatose is sterilised and we have found it to keep for days without perceptible change in condition or taste, even when kept at incubating temperature. Our analysis gave the following results: water, 44·97 per cent.; mineral matter, 7·49 per cent.; organic matters, 47·54 per cent. The proteids thrown out by sulphate of zinc amounted to 36·20 per cent. The nutrient value of albumose has already been pointed out in these columns and liquid somatose contains a very rich proportion of this soluble proteid. The mineral matter contained some amount of common salt. This preparation should be found to be of decided value in the sick-room.

(1) HIGHLAND MALT WHISKY; AND (2) COGNAC BRANDY.

(INNES, SMITH AND CO., 83, HIGH-STREET, BIRMINGHAM.)

We have examined the whisky with the following results: extractives, 0·48 per cent.; mineral matter, 0·015 per cent.; alcohol, by weight 39·30 per cent., by volume 46·59 per cent., equal to proof spirit 81·64 per cent.; acidity reckoned as acetic acid 0·024 per cent. The spirit shows excellent characteristics; it is mild and smooth to the taste, and its flavour is evidently derived from malt. There was no suspicion of *undesirable alcohols* or of the presence of injurious by-products. It is therefore well adapted for medicinal purposes. The Cognac brandy gave the following results on analysis: extractives, 0·725 per cent.; mineral matter, 0·005 per cent.; alcohol, by weight 38·22 per cent., by volume 45·41 per cent., equal to proof spirit 79·57 per cent.; acidity reckoned as acetic acid, 0·039 per cent.; volatile ethers (equal to alcohol) 2·02 parts, per 10,000 by weight. This is a well-matured spirit, soft and acceptable to the palate. It shows also a due proportion of volatile "wine ethers." Though somewhat sweet to the taste it contains no sugar or sweetening agent, the sweetness being due probably to the normal products of distilled wine subsequently mellowed by age. The spirit being undoubtedly pure and of satisfactory origin is accordingly suitable for use by invalids.

(1) SELAMA MINERAL WATER AND (2) SOAP.

(AGENTS, BARCLAY AND SONS, 95, FARRINGDON-STREET, LONDON, E.C.)

Selama water, drawn from a spring in Algeria known as Lake Moullah spring, presents a somewhat remarkable composition. It is practically a 1 per cent. solution of common salt, but with this mineral is associated an important quantity of silicic acid. Calculated as silica the amount is over 1 part per 10,000 parts of water. On this account the water slightly attacks the glass of the bottles containing it. It is said to possess certain medicinal properties, but to be more especially useful as an application to cuts or wounds or in eczema. It is said also to allay *irritation* and *inflammation* arising from insect bites or other causes. We make little doubt that this property is due to some extent to the silica present, since, as is well known, the silicates are powerful antiseptics. Silicate of soda is used, for example, for preserving milk. The other peculiar constituents of the water doubtless add to its antiseptic value in this respect. We have received a pamphlet recording several cases of skin disease under the care of a medical man in Algeria in which distinct benefit was claimed to have been gained by the external application of this water. The water has been tried *elsewhere, it is* said, with similar results. A soap is prepared containing, it is stated, 20 per cent. of "Selama" water. We do not understand how this can be unless the water was first concentrated, since the soap is very hard and practically dry, although it is of excellent quality.

EAU MINERALE NATURELLE DU BASSIN DE VICHY (SOURCE GUERRIER).

(GUERRIER PÈRE ET FILS, ST. YORRE, PRÈS VICHY, AND E. G. AFFLECK, 36, LIME-STREET, LONDON, E.C.)

According to our analysis this is a mildly alkaline water slightly charged with an excess of carbonic acid gas. The water is particularly soft to the taste. It is related to the celebrated Vichy water which, on account of its alkaline and saline constituents, is recognised to be of value in gastric catarrh and irritation. The sample before us gave the following results upon analysis: total saline constituents, 3·23 grammes per litre, comprising 2·50 grammes of carbonate of soda, 0·35 gramme of common salt, and 0·38 gramme of other salts chiefly of calcium. The water gives distinct evidence of lithium and traces of arsenic. Our analysis is not completely in accordance with that printed upon the label of the bottle in regard to the amounts; we found a smaller proportion of the salts indicated. As it is the water presents an interesting composition, especially in regard to the comparatively rarer constituents, manganese, strontium, phosphate of soda, arseniate of soda, and lithium. It was free from organic matters. It is probably serviceable in certain disordered conditions of the alimentary tract and in increasing the alkalinity of the blood. It is doubtless also of some tonic value owing to the manganese, iron, and arseniate and phosphate of soda present.

VICHY QUINA WINE.

(T. BAUDET, VICHY, AND E. G. AFFLECK, 36, LIME-STREET, LONDON, E.C.)

The analysis of this wine gave the *following* results: extractives, 13·46 per cent.; mineral matter, 0·35 per cent.; sugar, 6·92 per cent.; alcohol, by weight 14·82 per cent., by volume 18·25 per cent., equal to *proof* spirit 31·99 per cent. The wine is said to contain the natural salts of Vichy water. The reaction of the wine, as we expected, was acid, whereas *the salts of Vichy* water are alkaline, consisting *chiefly* of carbonate of soda. We cannot agree that whatever medicinal effects may be ascribed to the salts of Vichy water *the same effects* may be *also* ascribed to this preparation. Even were *it so* the proportion of *salts* present, as shown in the above analysis, is very small. The wine has a *flavour suggesting both cinchona* bark and *coca leaf*. We failed, however, to extract and to *recognise cocaine*, but we obtained a residue which gave the reactions of the active constituents *of* cinchona bark. The wine is described as "vin hygiènique, tonique, et fortifiant."

SOZOIODOL.

(H. TROMMSDORFF, ERFURT.)

We have received a beautiful crystalline specimen of the sodium salt of this interesting compound from the above firm. Sozoiodol, which, to give its chemical name, is di-iodo-para-phenol-sulphonic acid, forms an interesting series of salts with the metals, but the sodium salt seems best adapted for medical use. It forms an excellent antiseptic dusting powder. It may be regarded as an efficient substitute for iodoform, with the favourable difference that it possesses practically no objectionable iodous odour.

New Inventions.

THE "MARVELE" MILK BOILER OR STERILISER.

THIS is a very simple and effective device for the satisfactory boiling or sterilising of milk or other fluid. It consists of two saucepans one inside the other, the larger one being provided with studs inside which keep an open space uniformly between the inner and outer pan. The outer pan serves as a hot-water jacket, so to speak, to the inner pan. The inner pan is pierced with two holes so that the liquid contained in it will find its level in the other pan. Steam is generated fairly rapidly in the outer pan, which soon heats the contents of the inner pan. By this method the risk of burning milk is reduced to a minimum. *This alone is* a very important advantage, for milk if left to boil in an ordinary saucepan invariably gets burnt and acquires an unpleasant taste. The "Marvele" milk-boiler affords a very satisfactory way of *sterilising milk* or of cooking other fluids. It is possible even to concentrate milk in this boiler without the formation of products having a disagreeable taste. The inventor is Mr. Jacob Brown, of 130, South-street, Longsight, Manchester.

THE LANCET.

LONDON: SATURDAY, DECEMBER, 1, 1900.

WHATEVER obscurity may have originally surrounded the outbreak of peripheral neuritis which has now attained the proportions of an epidemic in Manchester and Salford and a large area around these towns, it is now certain that the mischief has arisen from the presence of arsenic in beer. We publish in our issue to-day a special account of the outbreak by Dr. T. N. KELYNACK, who has encountered many interesting cases amongst the very poor people attending the out-patient department of the Salford Royal Hospital, while others have been under his observation in the wards of the Manchester Royal Infirmary. Apparently the mischief has been going on for some months. The cases have been looked upon as simply "alcoholic multiple neuritis" The real cause of the neuritis, however, was traced eventually by Dr. E S. REYNOLDS to arsenic in beer, and Mr. C. H. TATTERSALL, medical officer of health of Salford, has called the attention of the Health Committee of Salford Corporation in his recent report to the large amount of sickness in the district from this cause. It was clear that the cases were of an altogether exceptional type and the conviction soon became irresistible that the symptoms were due to some special irritant or irritants taken in food or beverage. Most, if not all, of the patients were drinkers of beer in some form or other and accordingly the suspicion fell upon beer, and startling as it may appear arsenic was subsequently found in beer in easily detectable quantity. The clinical aspects of the outbreak are well described by Dr. KELYNACK to whose report there is appended an instructive analytical report by Mr. WILLIAM KIRKBY, F L S. Mr. KIRKBY, as will be seen, has found quantities of arsenic in various beers ranging from mere traces up to as much as 0·28 grain per gallon the results being expressed in terms of white arsenic or arsenious acid. These results relate to beers which were examined because they were suspected, but we have yet to learn the extent to which arsenical beer is being sold.

The outbreak is so serious that a very comprehensive investigation must be made. Suffice it to add for the present that Mr. KIRKBY has also turned his attention to certain specimens of brewing sugars; and the result of his inquiry has been that in glucose he found four parts of arsenic per 10,000 parts of the sugar, and in the "invert" sugar—i e, sugar obtained by boiling cane sugar with acid—he found three parts of arsenic in 10,000 parts of malt substitute In a communication from Professor DELEPINE and Mr C H. TATTERSALL which we also print in our present issue, it will be seen that these gentlemen report the presence of arsenic in beer, glucose, "invert" sugar, sulphuric acid, pyrites, but not in the hops, preservatives, gypsum, water, whiting, maize, sago, or tapioca. These results are conclusive and may well cause alarm. The surprise is that wholesale poisoning has not previously occurred. One thing is certain, and that is that for years past brewers have employed both glucose and "invert" sugar for brewing beer. Further, these sugars or malt-substitutes have been obtained by acting upon starches and cane sugar with sulphuric acid. Further, again, and still more important is it to bear this in mind, ever since sulphuric acid was made from arsenical pyrites arsenic has been a common impurity of the acid. Under these circumstances it is surprising that peripheral neuritis traceable to arsenical poisoning due to the drinking of modern beers made from malt substitutes has hitherto not been observed even in individual cases. It is hardly conceivable that poisoning from this cause can have previously reached the dimensions of an epidemic, as in the present instance. It is said, however, that very large consignments of "invert" sugar from America have recently been employed by brewers in this country, and this may possibly throw some light on the present unfortunate occurrence, which may be attributable to transatlantic sources hitherto unused.

The whole story illustrates the great dangers that may arise from the introduction of substitutes in the course of the preparation of foods and beverages. It would appear that the use of malt substitutes is a matter of expediency rather than of economy. It is a mistake to suppose that the use of "invert" sugar, glucose, or cane sugar is cheaper than their equivalent of malt. Beers brewed with sugar are more brilliant and stable than beers brewed with malt alone. Moreover, the beers so obtained are of a lighter character and have a more distinctive flavour. The materials used for the preparation of glucose in this country are maize, sago, and rice. These are boiled with dilute sulphuric acid, either with or without pressure, the starch in them being thus rapidly hydrolysed into dextrine and maltose, which in turn are rapidly displaced by glucose. The resulting acid liquid is neutralised with whiting and the main portion of the gypsum thus formed is allowed to subside. The liquid after filtration is finally concentrated. It is clear from the details of this process that any arsenic occurring in the sulphuric acid would remain in the syrup or in the ultimately crystallised product. Arsenical poisoning has before been traced to the use of sulphuric acid in the course of manufacturing certain preparations intended for human consumption. About five months ago, for example, we reported that arsenic had been found as a common impurity of phosphate of soda, which impurity had been derived from the sulphuric acid employed in the manufacture, and it appeared also that phosphate of soda formed the basis of a popular effervescing drink. The consumption of phosphate of soda, however, is comparatively trivial and unimportant, whereas in the case of beer the danger of employing impure sulphuric acid in the elaboration of products intended for human consumption on a large scale is specially obvious. It seems to us that this epidemic affords a fresh and startling argument for the interdiction of substitutes, unless very definite steps be taken to secure the absolute purity of such substitutes. It is noticeable that the Pure Beer Committee of four years ago did not suggest the awful possibility of an epidemic of arsenical poisoning arising through the use of malt substitutes in beer. This

Committee was directed to inquire into and to report upon, the question whether legislation is required "*to prevent the use of deleterious substances in the manufacture of beer*; and whether the materials of which beer may be composed can be defined by law without undue interference with the liberty of brewers to use wholesome materials in brewing." The italics are ours Of course, the Committee directed its attention mainly to the wholesomeness of the substitute, without paying apparently the slightest regard to the processes by which such substitutes are made and the possibilities of poisonous materials gaining access to them It seems to us that the Committee has missed an important aspect of the subject of inquiry But it is curious how exactly the words contained in the reference to the Committee apply to the present unfortunate epidemic of arsenical poisoning in Manchester and its neighbourhood.

The question remains when and where will the mischief cease? Legislation, we most emphatically agree, is undoubtedly required "to prevent the use of deleterious substances in the manufacture of beer" The interests of the public health urgently call for it, and it is the immediate duty of the Government to institute a thoroughly exhaustive inquiry The question must be settled as to who is culpable and what course must be adopted to render a recurrence of disaster absolutely impossible

◆

THE discussions which are now constantly taking place in Ireland in reference to university education and the feeling that important changes, fraught with far reaching consequences, may at any time be brought forward, are having a most baneful effect on higher collegiate work in that country As a natural result of the present uncertainty the sons of many Irishmen who would under ordinary circumstances be educated at home are being sent to English or Scottish Universities, because their fathers, remembering how suddenly they, through Mr DISRAELI'S action in destroying the Queen's University of Ireland in 1879, were left as graduates of a non existing university, are determined that their sons shall not through coming legislation be treated in a similarly scandalous way Again, owing to the same causes, the present Queen's Colleges, which are in all respects Government institutions, are being starved Friendly statesmen of both political parties feel that as soon as they attempt to propose increased grants for any of these educational centres the Nationalist Members of Parliament will offer every form of opposition until the Roman Catholic demands have been met

The annual grant paid by Parliament to the Queen's Colleges of Belfast, Cork, and Galway remains the same in amount as it originally was when in 1849 these institutions were established by SIR ROBERT PEEL, but this endowment is totally inadequate to cope with the increased demands now made for teaching new subjects which were not required in former years We can best illustrate this by examples from the medical faculty In two of the colleges there is no separate professorship of physiology, the chairs of anatomy and physiology being combined; in Belfast the same state of matters existed until 1893, when, through the munificence of Mr DUNVILLE D L, the chair of physiology was established and endowed In none of the three colleges is there any endowment for a professorship of such an important subject as pathology, the lecturer receives the students' fees But in Belfast, there is a pathological laboratory. Again, in none of the three colleges is there a chair of public health, and the attempts to meet the demands of the times in this department—so useful to the nation—are certainly anything but efficient There is no provision in any of the departments of the medical curriculum for demonstrators or assistants, they must either be dispensed with or the professors must provide them out of their own resources New laboratories are needed in many of the departments, such as biology and pharmacy In the Belfast College in the year 1891 the Board of Works commenced, under the sanction of the Treasury, the erection of a building for the department of chemistry, but after spending £5500 the Treasury declined to give the remaining £3200 for the completion of the building unless a local contribution was made towards the object The Government's action was intended, no doubt, to prove a strong stimulus to local activity, but it has unfortunately resulted in the chemical department of Queen's College, Belfast still remaining in an unfinished condition With the great progress in medical science one new department after another has to be established and the necessary expenditure incurred has to be met by the College authorities out of the same small annual financial grant that they were receiving years ago, for the Government absolutely refuses to make any new and additional endowment

The argument that Ireland should rise to its obvious duties and contribute more to the funds of the local colleges has force, but, on the other hand, the reply is an obvious one The inhabitants before they will give money to the local colleges, must be assured of the stability of the institutions, and of the probable permanence of the policy in accordance with which they were founded The fact that these colleges are State colleges militates against them The Belfast citizens, for example have no voice whatever in the government of Queen's College, Belfast There is no senate or board of governors (as is the case in the Owens College, Manchester, and in Birmingham) in which some of the leading citizens have a share, and consequently it is only natural that they do not take that special personal interest in the College which they certainly would had they some responsibility for its management Even under the existing circumstances the citizens of Belfast have given thousands of pounds to the College, and being proud of their rich and prosperous city, they would certainly do more towards endowment if they felt sure of their ground But that is what they cannot feel The State established the Queen's Colleges in Ireland and entirely controls them It should equip them properly, and it does not Medical science in particular suffers under the present conditions, because the enormous progress that has recently taken place in medicine calls for increased endowment

◆

WE should hardly be disposed to reckon office boys as a class among pioneers of sanitary progress To an individual of this order, however, seemingly belongs the honour of having initiated a widespread and much needed agitation for sanitary reform in no less a place than the Royal borough of

Windsor. In June of last year the youth in question handed to representatives of the local press a report by the medical officer of health of the borough, Dr. E. CASEY, which was to be presented and considered at the next meeting of the Windsor Town Council. After that meeting the press accounts, which set out Dr. CASEY'S report in full, caused great astonishment to certain members of the town council, who learnt for the first time that the medical officer of health had been calling attention to the grossly insanitary condition of a large group of cottages in Windsor, but that all his observations on this subject had been omitted when his report was read at the town council meeting. Inquiries followed, from which it appeared that, failing specific directions from the Sanitary Committee, discretion as to what parts of reports by the medical officer of health should reach the town council and the public was habitually exercised by the town clerk. Application was then made by certain residents to the Local Government Board for inquiry.

As a result, that Board has lately issued a report, which we review more fully elsewhere in our present issue, by Dr. H. T. BULSTRODE, who has not only locally investigated the current methods of sanitary administration, but has studied in detail the various sanitary shortcomings of the borough. This report has created, as no doubt it was intended to create, a great stir in Windsor. The inhabitants have had brought to their notice that their town is lacking in many essentials to the healthy life of a modern community which can be provided as easily for their ancient borough as for newer towns of much less importance. For example, the borough is without an isolation hospital or a disinfecting apparatus, and this notwithstanding the special need for measures to control infectious disease in a place which is at once a Royal residence, a military station, and a resort for visitors from all parts of the world, while it is also close to one of the most famous public schools of the country. In addition, Windsor has now been given officially to understand that its sanitary administration in ordinary day-to-day matters has been weak in the extreme; that the by-laws of the place are unknown even to officials of the town council; that their town abounds in nuisances due to accumulation of refuse near to dwellings; and that the conditions under which the poorer classes live are in many cases about as bad as they can be. Rows of houses which by reason of their dilapidation, inside and out, and of their unwholesome surroundings should long ago have been condemned as unfit for habitation, have year after year been permitted to be occupied, notwithstanding representations more or less forcible by the officers of the sanitary department. So persistent have been the influences exerted against improvement in such matters that these officers have come to look upon reform as hopeless, and, in the words of the report, have "become disheartened" and have learnt to adopt "apologetic attitudes." Notwithstanding much indignation which has been expressed at Dr. BULSTRODE'S indictment, there are signs that it has had effect. Already, it would seem, something has been done by way of amendment by the town council, which, we are glad to learn, has after the recent elections been reinforced by new members who have pledged themselves to comprehensive measures of reform. Having regard to the circumstances set out in Dr. BULSTRODE'S report, the resignation of the town clerk, which was recently announced, is, from the view of sanitary progress, not wholly to be regretted, notwithstanding that Mr. LOVEGROVE has doubtless in other respects established substantial claim to the gratitude of the people of Windsor. Concerning the fate of the office-boy we are ignorant; but as a happy accident enabled him to inaugurate great benefit to his fellow-citizens we should be glad to learn that he has been rewarded.

Readers of THE LANCET of 1885 will find in Dr. BULSTRODE'S official report ample justification of the action which in that year we felt it our duty to take when we brought before the public the backward state of sanitary affairs in Windsor. As a result of careful inquiries by a Special Commissioner of THE LANCET we then called attention to a number of conditions urgently demanding remedy, which, 15 years ago, could readily have been applied by a town council willing to exercise a reasonable amount of determination and common-sense. In particular we urged on the local authorities the need for careful investigation of the unhealthy and degrading conditions under which a large portion of the people in Windsor were living and for efforts to ameliorate them. The Rev. ARTHUR ROBINS, then rector of Holy Trinity, Windsor, whose acquaintance with the moral and social conditions of the Windsor poor was intimate, aided our efforts by the most determined advocacy, but our warnings, we fear, in the long run had small effect. In particular, the house-to-house survey which we suggested as the first essential to sanitary progress was not adopted. The town council had learnt "how not to do it," and continued content in applying that knowledge. Their officials at that time indeed furnished us with admirable examples of the "apologetic attitude" which since has so impressed the inspector of the Local Government Board. We recall these facts in no spirit of self-complacency, but because they may serve to remind the people of Windsor and their representatives, now suffering from another public exposition of the shortcomings of the borough in a sanitary sense, that the best way in the long run is to face, and not to ignore, the difficulties which beset reform. We are glad to learn from local sources that there is a prospect that in future the ostrich-like policy from which Windsor has suffered in the past will be definitely abandoned.

Annotations.

"Ne quid nimis."

BACTERIOLOGY AND RELIGIOUS RITES.

THE fact that bacteriology is quite a modern science, whereas religious rites and ceremonies date back as far as historical records will allow us to go, sufficiently explains the want of harmony between them. It would, indeed, have been a proof of marvellous prophetic intuition if those who first initiated religious ceremonies had foreseen and prepared for discoveries to be made many centuries later. Several of our correspondents have expatiated on the risk attending the promiscuous use of the communion cup. This, however, is far from being the only risk of this description. The holy water in Roman Catholic churches is quite as serious a matter. The shallow shell-shaped receptacle is placed barely three feet or so from the floor, so that the dust stirred up by the feet or shaken off from the persons who pass by readily falls into it. Innumerable *fingers*, not always *scrupulously* clean, are dipped into the water. Also, it is just at the moment of danger and trouble that the faithful are most prone to resort to their church for prayer and consolation. Coming straight from the sick bed of some loved parent or friend, can we expect that the hands are always thoroughly disinfected before they touch the holy water? In Spain especially, and during the great cholera epidemic of 1885, we have noted that the holy water was absolutely dirty and living organisms could be seen with the naked eye, so what the microscope would have revealed may well be imagined. Now the fingers convey this water to the forehead and breast of the devotee, and of course the mouth might also be touched with the same fingers. But we do not see that there would be any lack of reverence shown if this holy water was changed more frequently, nor are we aware that it would be a sacrilege to mix it with some strong antiseptic solution. Again, at the Ahmed Mosque of Constantinople there is a small piece of the black stone brought from the Kaaba of Mecca. Against this piece of stone the true believers come and rest their heads for a considerable time. By so doing it is supposed that various illnesses can be cured, and as there are certain affections that can be favourably affected by the force of suggestion the results sometimes attained seem to confirm this superstition. But though a hard stone is less dangerous than water and germs of disease deposited upon its surface would soon be oxidised, still patients following each other in rapid succession might convey to one another pathogenic microbes. The same may be said with regard to the kissing of the toe of the bronze statue of St. Peter at St. Peter's, Rome. Would it be too much to ask that this stone, this bronze toe, and other similar objects of reverence and adoration should be frequently wiped with a rag moistened in an antiseptic solution? Why should science and religion be divorced one from the other? If we have been endowed with the intelligence to foresee a danger, may we not, with all due reverence, take the necessary precautions to ward off this peril. With regard to the communion cup, Count Leo Tolstoy, in his recent novel "Resurrection," decribes the celebration of the Liturgy in the chapel of a Russian prison. Here the priest cuts the bread into little pieces and dips them in the cup containing the wine. Then with a spoon he places the piece of bread and wine into the penitent's mouth. Thus there is no drinking out of the cup and it would be much easier to have a clean spoon for each communicant than a separate cup. This is the general practice of the Orthodox Greek Church and one which lends itself better to sanitary precautions than that of the English Church and her sister communions as we have already pointed out.[1]

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

"IT is desirable that further help up to a minimum of £25,000 may be given before Dec. 15th next" is the concluding sentence of a special appeal which has been issued with the third annual report of the Prince of Wales's Hospital Fund for London. Although the report is a very satisfactory one from the point of view of work done the receipts do not reach the progressive standard which the needs of the hospitals call for. This is especially regrettable at a time when the hospitals of London are suffering from a lack of financial support by reason of the heavy drain upon the charitable purse in other directions. The total sum distributed in 1899 amounted to £42,000, with a total cost of management and collection of about 3½ per cent. Of this sum £26,000 have been given as annual grants and the remainder as donations. Deducting from the total sum £1000 which were given to convalescent homes, and the balance of £41,000 compares with £31,500 of the previous year. The sum collected in the Diamond Jubilee year was £56,826. The report of the distribution committee states that arrangements have been made for the re-opening of 45 beds next year. This number added to the figures of the two previous years gives a total of 287 beds made available to the poor of the metropolis by the agency of the fund. As the demands upon the hospitals will be greatly increased by reason of the returned sailors and soldiers from South Africa, independently of the ordinary increase which now takes place year by year, every effort should be made to obtain the sum which the executive committee of the fund appeal for; and now that the fund has shown itself after three years of usefulness to be able to work with a minimum of expenditure not only subscriptions and donations but legacies ought to fall to its share. With regard to the important question of the rating of hospitals the report of the general council of the fund states that "in the course of the present session a petition will be presented to Parliament by the Central Hospital Council calling attention to the heavy rating of hospitals. In support of this, on behalf of the fund, a petition has been forwarded in accordance with the instructions of the executive committee, expressing the sympathy of all concerned, and their desire to see the rating of all recognised London hospitals abolished." Included in last year's list of subscribers and donors are the following annual subscriptions:—The Prince of Wales, £105; the Princess of Wales, £25; Princess Victoria of Wales, £5; the Duke and Duchess of York, £21; Princes Albert and Edward of York, £2 2*s.*; Princess Victoria of York, £1 1*s.*; the Duke and Duchess of Fife, £50; the Duke and Duchess of Teck, £10; Captain Prince Louis of Battenberg, R.N., £1 1*s.*; Princess Louis of Battenberg, £1 1*s.*

THE APPOINTMENT OF HONORARY MEDICAL OFFICERS TO INFIRMARIES.

IT is much to be regretted, at a time when *esprit de corps* of the profession is in the ascendancy, that antiquated methods of election of honorary officers to our infirmaries should still exist. When a body of subscribers, as well as presidents, vice-presidents, and boards of management, have to be solicited for votes it is canvassing, and canvassing of a distasteful nature which might deter well-qualified candidates from entering the field. We would be the last to deprive anyone of the franchise or to remove any privileges which subscribers may enjoy, but surely these persons might depute the election of honorary officers, when occasion requires, to a body elected by themselves. At an annual meeting when the subscribers are assembled after electing president, vice-presidents, and board of management, surely an elective body could be appointed from among the subscribers to act for the following year, and such subscribers, together with the board of management, would form a body suitable for the purpose. In some cities and towns we believe that this has been done and that it works well; why cannot every town that is proud of its hospital do the same? We are prompted to make these remarks in consequence of the election of an honorary medical officer to the Royal Albert Edward Infirmary, Wigan, which took place on Nov. 14th. Three eligible gentlemen had been nominated and provision had been made for taking a poll if necessary. One of the candidates (Dr. F. Rees) who had the unusual privilege of addressing the subscribers (electors), questioned the right of many of the gentlemen present as representatives from the works (because it was alleged the working men themselves had not elected them) to vote, and some acrimonious remarks were made. He also moved the adjournment of the meeting, but this was defeated by a large majority. An allegation having been made that the board of management had not allowed the proper representatives of works to be on the list or register of representatives sent in each year, the chairman of the board of management said that he had no knowledge of any name being on the list of voters that ought not to be on. He understood from the secretary that the names of the works' representatives were sent in at the proper time and put on the register, and he took it from a business point of view that those names were those of the nominees of the works from which the money came. As far as the board of management was concerned he did not agree with the speaker (Dr. F. Rees) that these men had been improperly elected. It was for the men at the works to put the matter right themselves. He thought that the method of electing a medical officer was not very dignified and it might very well be left with an elective body. It would be more dignified for the profession and more useful to the institution. The election afterwards proceeded by a show of hands, the successful candidate having a large majority. A poll, however, was demanded, but on the proxies being handed in it was withdrawn.

---

[1] THE LANCET, Oct. 13th, 1900, p. 1088

AN INTERESTING ACTION FOR MALPRACTICE AGAINST A DENTIST.

THE last issue of the *British Journal of Dental Science* contains a short account of an important action tried before a jury in the Lord Mayor's Court against a dentist for alleged negligence. The facts of the case, as gathered from the report and also a letter from the defendant, are briefly as follows. The tooth in question was a mandibular molar. The cavity in this was dressed with carbolic on a Tuesday and on the following Thursday the nerve canals were cleaned out and filled with a dressing of carbolic acid and iodoform. A cement filling was inserted and the plaintiff was told to return if any pain or trouble occurred, which he did not do. It was only intended to retain this tooth for a few weeks. The same night pain commenced and by the following morning when seen by his medical man there was so much swelling as to cause trismus His temperature was stated to be 104° F. and it was also said that it was impossible to remove the tooth. The face was poulticed on the outside for three days and incisions were made both inside and outside the mouth. The tooth was allowed to remain for three weeks and even during this time no attempt was made to remove the filling. The dental surgeon who gave evidence in support of the plaintiff stated that it was wrong practice to put a cement filling in a tooth if the nerve was dead, and stated that such teeth required to be dressed with antiseptic wool sometimes two or three times before being filled. He also stated that with a temperature of 104° it would have been wrong to administer nitrous oxide and to remove the tooth. Other evidence was given on both sides and a verdict was returned for the plaintiff with £40 damages. This case is of great interest because if such a decision could be upheld there are few dentists who would not be liable to be mulcted in damages in performing such an operation, since septic inflammation must always be regarded as a possible complication. The operation as performed by the dentist was a perfectly justifiable one; he cleared the pulp canals of septic matter, placed in a dressing of antiseptics, and sealed them with a plastic filling which he would have removed if pain had occurred. This was stated to be wrong practice by the dentist called in support of the case, but it is nevertheless the method adopted by the best dental practitioners of the day, while the method stated as correct by the dentist is one which, perhaps, may be regarded as a relic of the past. In our opinion the defendant was in no way to blame. A temperature of 104° is no bar to an anæsthetic if an operation is necessary. Still further, there is no reason whatever that should have prevented the removal of the tooth. If a consultation had taken place between the dentist and the medical practitioner in all probability the tooth would have been removed at an early date and the burrowing of pus prevented. The treatment, too, of applying poultices to the outside of the face is open to much criticism. In the report before us there is no mention of an appeal having been applied for, but it is to be hoped that the case may be heard of again before a higher court and with evidence given by a practitioner holding not only dental but also medical qualifications.

GLASGOW UNIVERSITY CLUB, LONDON.

THE winter dinner of this club will be held at the Café Royal, Regent-street, on Wednesday, Dec. 5th, at 7.30 P.M., Professor Sir Hector C. Cameron, M.D. Glasg., in the chair. Lord Lister and Surgeon-General J. Jameson, C.B. (Director-General of the Army Medical Service) have promised to attend, and amongst the club guests will be Major Babtie, R.A.M.C., whose conspicuous bravery at the battle of Colenso in the early part of the present war secured for him the Victoria Cross. Major Babtie, who is a graduate of Glasgow University, has just returned from South Africa, and we anticipate that his welcome home by his old friends and fellow-students is likely to be a hearty one. Members who intend to be present at the dinner should communicate immediately with the honorary secretary, Mr. Norman MacLehose, 13, Queen Anne-street, Cavendish-square, W.

THE DIAGNOSTIC VALUE OF KERNIG'S SIGN IN CEREBRAL AFFECTIONS.

DR. PAUL ROGLET in his *Thèse de Paris* (1900) makes an important contribution on the pathogenesis and the diagnostic value of Kernig's sign in cerebral affections. In 1884 Kernig described the presence of a certain clinical sign as characteristic of meningitis—viz., the inability to extend the knee fully when the patient was seated in bed with the thigh extended at right angles to the trunk. The cause of this functional inability was due to a contracture of the flexors of the knee. When the patient, however, was allowed to lie on the back this contracture disappeared and complete extension of the leg at the knee-joint was possible. Dr. Roglet made a careful series of observations on this point in 35 patients and has concluded that the sign is not exclusively present in meningitis but may be met with in other forms of cerebral irritation. In 85 per cent. of cases of meningitis, whether due to meningococci, pneumococci, streptococci, or staphylococci, it was easily elicited. In tuberculous meningitis it is somewhat less frequent. It makes its appearance when the disease is well-established, but it varies in intensity from day to day, and a case is recorded by Dr. Roglet where it was found to be present in a patient convalescing from cerebro-spinal meningitis. Spinal meningitis need not be present co extensively with cerebral to give rise to this sign, for in one fatal case at least of meningitis followed by necropsy no indication of spinal implication could be found though the sign was easily elicited during life. The pathogenesis of this sign is thus explained. In a normal and healthy subject seated in a bed and with the legs fully extended and at right angles to the trunk the flexor muscles of the knee are stretched to their utmost and their elasticity is thus completely exhausted. If, however, owing to some irritation of the spinal (motor) nerves supplying these muscles, there is produced an increase in the tonicity (hypertonicity) of the muscles the result is that the elasticity of the muscles is lessened, their length is diminished, and their fullest extension is no longer possible. Indeed, under such conditions as meningeal and nervous irritations, not only does this result appear in the form of Kernig's sign, but the attempt to suddenly extend the knee (and with it the flexor muscles of the knee) results in a momentary augmentation of the irritability of the muscle and a consequent slight increase of the contracture. This last condition is familiar to us under the forms of ankle-clonus and rectus clonus, both of which may result from cerebral lesions followed by descending degenerations of the pyramidal tract.

BRITISH CONGRESS ON TUBERCULOSIS.

THE British Congress on Tuberculosis will be opened in London by the Prince of Wales on Monday, July 22nd, 1901, and will be continued on the following days of the week. The Congress will have four sections—pathology, medicine, State medicine, and veterinary medicine—which will meet on the mornings of Tuesday, Wednesday, Thursday, and Friday, and Saturday will be devoted to excursions. Further particulars can be obtained from the honorary secretary-general, 20, Hanover-square, W. The subscription for members of the Congress will be £1, which will include a copy of the Transactions. A fund is being formed to defray the expenses connected with the Congress, which must be considerable; it already amounts to £500, but at least five times this amount will be required.

THE HOUSING OF THE POOR IN BERLIN.

IN Germany, as in England, the development of modern industries has caused a widespread migration of the rural populations to the large towns. The result has been overcrowding, which is denounced by all the sanitary authorities of the Empire as a great public danger. Of course, the rents have gone up by leaps and bounds, and now the poor man can hardly lodge himself and family. Dr. Schwalbe, of the Berlin Statistical Bureau, calculates that a man with an income of £45 per annum has to give 24 10 per cent. of this income for rent. A man whose income varies from £45 to £75 pays 22 11 per cent. of his income for rent, while a person with an income of £1500 only pays 9 20 per cent. for rent. At Hamburg the position is even worse, for there out of incomes of from £30 to £60 no less than 25 5 per cent goes for rent, while some 30 years ago the proportion was only 18 8 per cent. Under such circumstances it is not surprising to hear that no inconsiderable section of the population is homeless. A census was taken in 1895, and then it was found that in Berlin 77 2 per 1000 men and 39 2 per 1000 women had no permanent home. Herr A. Braun, a member of the Berlin Sanitary Board, says that children of both sexes are often obliged to sleep in the same room as their parents and that lodgers are sometimes taken in and the children have to sleep in the same beds as these lodgers. Modesty and decency cannot survive under such conditions. The average infant mortality in Berlin is 31 5 per cent, but while it is only 8 6 per cent in the wealthy districts it is 52 27 per cent in the poorest districts. The vital statistics of Breslau, of Munich, and of other towns all tell the same tale; and not only is the health of the populations affected but their moral condition is likewise deteriorating. The herding together of the factory hands in large towns has, we are told by more than one authority, produced a state of barbarism and bestiality that exceeds anything known before. There is a self evident analogy between these complaints from Germany and the terrors of Hooliganism in England. The poor agricultural labourer may be stupid and dull, but if the poorer sections of the labouring population of the large towns are more quick-witted their temptations are much greater and they become much more vicious. This is a sanitary and a social problem arising from modern industrialism which must be faced by all great commercial communities, whether English, French, German, or American.

MEDICAL OFFICERS FOR THE HIGHLANDS AND ISLANDS OF SCOTLAND.

WE publish three advertisements which have appeared in a Shetland paper.—

WANTED by the School Board of Walls, Sandness, &c., Shetland, a certificated Teacher (Male or female), for FOULA Public School, Salary £70 per annum, with house and garden rent free. Applications with testimonials to be lodged with the Clerk of the Board, on or before 3rd December next

WANTED by the Parish Council of Nesting, &c., Medical Officer for Lunnasting, Whalsay and Skerries Salary, £25 per annum, to include medicines to Paupers, with fees for Vaccination prescribed by Sect 2 of the Vaccination Act, and fees for quarterly visits to Pauper Lunatics in private dwellings —JOHN IRVINE, Clerk.
Whalsay, 14th Nov., 1900.

WANTED, by the Parish Council of Nesting, &c, Medical Officer for Nesting District. Salary, £15 per annum to include Medicines to Paupers, with Fees for Vaccination prescribed by Sect. 2 of the Vaccination Act, and fees for quarterly visits to pauper lunatics in private dwellings JOHN IRVINE, Clerk.
Whalsay, 14th November 1900

They show very well the relative values which are placed upon the services of a medical man and a teacher certificated to teach elementary education. Now though we do not for a moment suggest that the teacher's salary is any too much, for even including the house and garden it is only about as much as a butler gets, yet the contrast between the sum which the teacher gets and that allotted to the medical man is absurd. The teacher has regular hours; his clients come to him; and he is not compelled to rise at all hours in all weathers to find his way across bogs and seas with life or death perchance depending on his actions. Presumably he will get at least a month's holiday and no one will have to do his work while he is away, for there will be no work to do. We can only implore candidates for the medical posts to make very sure of three things which we have already insisted upon before—notably in our issue of Nov. 10th—namely, fixity of tenure, a free annual holiday, and adequate salary.

INSANITY AND GLYCOSURIA.

DR. DAVID BLAIR of the Lancaster County Asylum states in the *Journal of Mental Science* for October that glycosuria, though it might be expected *a priori* to be common, is really quite rare, among the insane inmates of public asylums Dr. Hale White found traces of sugar in the urine in only 2 6 per cent of the patients in the Surrey County Asylum Glycosuria is relatively prevalent among nervous and highly emotional races, while it is rare in stolid and unemotional nations such as the Chinese. Worry and anxiety in highly intellectual individuals will produce temporary glycosuria. In lunatics who, having already passed through the storms and stresses of emotion during the prodromal stages of insanity, are thereafter admitted into asylums the causes favouring glycosuria are passing, or have passed away, and hence sugar in the urine is seldom met with. Two cases illustrative of the above facts are recorded, one that of a young woman who had been jilted by her lover and the other that of an elderly woman, aged 52 years, who had been troubled with domestic worry, in each of which the period of acute emotional suffering and melancholia was attended with glycosuria, which, however, vanished as the melancholia passed off. In 10 per cent of recent cases of melancholia glycosuria has been met with, while in mania it is said not to have occurred once. Dr. Blair has specially examined the urine of several epileptic lunatics but never once detected sugar. In no case of insanity treated with thyroid extract, could any sugar be detected in the urine, although the thyroid extract administered contained a small amount of lactose. No special treatment is needed for glycosuria in the insane except careful dieting and the practical exclusion of sugar and carbohydrates from the food.

NEW EDITIONS OF SCIENTIFIC WORKS.

IN another column will be found a letter from a correspondent under the above heading, suggesting that publishers when issuing a new edition of a scientific work should contemporaneously issue an appendix containing merely the alterations and additions to such work. Those, he says, who could afford to buy the complete edition would still do so, while those who possessed a former edition but could not afford the new one would buy the appendix. We are not so sure of the position as is our correspondent. The issue of an appendix would be a very good thing for the purchasers, but we have to consider not only the purchasers but also the publisher, to say nothing of the author, who, except in the case of a popular novelist, makes, as a rule, less out of the book which is the creation of his brains than anyone else. To print a book with alterations included in the body of the text and another book with those alterations printed separately, including all cross references such as, for instance, "Page 15, line 30, for 'to' read 'at,'" would necessarily entail two different settings of type and a proportionate increase in expense. On the whole, then, we do not think the plan feasible. While on the subject of new editions we should like to point out that it would be a great convenience if publishers would print upon the fly-leaf of any new edition the dates of the issues of former editions. One firm at least, Messrs. Macmillan, do this, and they deserve credit for so doing, but we should like to see the practice general.

THE FLUCTUATIONS IN OUR POPULATION.

AT a meeting of the Royal Statistical Society, held on Nov. 20th at the society's rooms, 9, Adelphi-terrace, Strand, W.C., a paper on the Distribution of Population in England and Wales, and its Progress in a Period of 90 Years from 1801 to 1891 was read by Mr. T. A. Welton, F.C.A. The writer commenced by depicting the position in 1801, when London contained not more than 922,000 inhabitants, and the next largest place (Manchester) about 91,432. There were 112 towns outside London with populations descending from that figure to 4000, and amounting in all to 1,400,762. The remaining towns distinguished in the tables ranging as low as 1000 inhabitants, contained 774,255 inhabitants, and there were populous industrial areas extending over 346,796 acres, and containing 227,593 inhabitants, besides which portions of the areas surrounding towns, but not actually parts thereof, were also populous. The bulk of the country was, however, thoroughly rural, over 34,000,000 acres being inhabited by 4,721,252 persons out of the total population of 8,892,536. At this date 36 per cent. of the people lived in towns of 1000 inhabitants and upwards, but in 1891 64 per cent. of the people lived in towns exceeding 4000 in population. The writer pointed out that there was a decline in rural populations since the year 1851, following a severe check to their increase in the period 1841 to 1851. This contrasted strikingly with a specially great increase of rural population in the years 1811 to 1821, the period marked by the cessation of the continental war. In sympathy with both phenomena, the less progressive towns greatly slackened in their increase during the 50 years 1841 to 1891, and showed a special tendency to increase in the years 1811 to 1821. As respects the more progressive places, there appears to have been latterly a slackening in the rates of increase of the older centres, say, towns which in 1801 had not less than 2000 inhabitants, but a fully sustained increase in the populations of those rising places which had not attained importance in 1801.

THE RELATION BETWEEN CARDIO-VASCULAR AND RENAL DISEASE.

THE *Philadelphia Medical Journal* of Oct. 27th contains a useful paper by Dr. A. O. J. Kelly on this intricate and at the same time practical question. In the advanced stage of granular kidney, when the nutrition of the heart begins to fail and the circulation becomes embarrassed, cardiac symptoms—cardiac asthma, œdema of the lungs, gastro-intestinal disturbances, oliguria, and anasarca—are most prominent and the pulse loses some of its high tension. To the cardiac hypertrophy dilatation supervenes and the right ventricle undergoes changes similar to those of the left. The mitral valve may become incompetent from dilatation and a murmur may arise. Thus primary heart disease is simulated. On the other hand, valvular disease may in its turn simulate renal disease. Owing to cardiac debility the murmur may be temporarily absent and albumin and casts may occur in the urine. Given, then, a patient with failure of cardiac compensation, hypertrophy and dilatation of the heart such that it is well-nigh impossible to determine which side is especially involved, and albumin and casts in the urine, with or without murmurs—is his affection primarily cardiac and secondarily renal, or *vice versâ*? The question is extremely difficult to settle off-hand. But in the majority of cases the diagnosis can be made by bearing in mind that in congestion of the kidney the casts are usually hyaline and that the amount of albuminuria varies with the state of cardiac activity, increasing and decreasing with impairment or improvement in the action of the heart. Again, if the urine remains albuminous despite the subsidence of signs of congestion of the liver, the spleen, and the serous cavities, if the specific gravity falls, and if in addition to hyaline a few granular casts and possibly some erythrocytes are found, there is evidently nephritis. The therapeutic test is of great importance. If the administration of digitalis which is urgently indicated produces marked improvement with disappearance of casts and albumin from the urine the condition is renal congestion, but if with cardiac improvement they do not disappear nephritis is present. This conclusion can be confirmed by examination of the cardio-vascular system now that compensation has been more or less restored. In the treatment of renal disease the cardio-vascular condition will need careful attention. In the stage of hypertrophy the well-known hygienic rules should be followed. Dr. Kelly advises the use of proteids in moderation. Some easily digested meat should be taken once a day. Eggs are very suitable. The only medicine required is an occasional saline purge to lower blood-pressure, but when cardiac failure begins medication is called for. Dr. Kelly strongly recommends nitro-glycerine in conjunction with caffeine—$\frac{1}{100}$th of a grain of the former in tablet or solution and three grains of the latter simultaneously three times a day. The nitro-glycerine not only lowers arterial tension but reduces the albuminuria, but it should be borne in mind that the pressure is not to be reduced to normal; some increased pressure is desirable. Caffeine acts as a gentle cardiac stimulant and as a diuretic. By means of this treatment Dr. Kelly has obtained good results. Dyspnœa, vertigo, and headache disappear, even in advanced cases. It is well to continue the treatment for from four to six weeks and then to interrupt it for a week or 10 days if the condition of the patient permits this. This treatment will also ward off an attack of uræmia (shown to be imminent by headache, vertigo, restlessness, foul breath, coated tongue, and diarrhœa). When there is no decided cardiac debility Dr. Kelly believes that digitalis does more harm than good; it is indicated when marked cardiac dilatation and failure of compensation arise. It should be given in large doses and if good results be not obtained within four days strophanthus should be substituted. Strychnine is very efficacious, not only on account of its general effect, but also because of its action on the heart.

THE PARISH OF ST. GEORGE-THE-MARTYR, SOUTHWARK.

IN his annual report to the Vestry of St. George-the-Martyr, Southwark, Dr F. J. Waldo, the medical officer of health, calls attention to the fact that during 1899 diarrhœa caused a greater mortality in the parish than any other zymotic disease, 102 deaths being attributed to this cause. Of this number 75 were under the age of one year, 21 were between one and five years, and six were at the age of five years and upwards. In addition to these 102 deaths from diarrhœa there were 39 deaths from gastro-enteritis. The predominance of mortality from diarrhœa over that due to other zymotic diseases was not peculiar to the year 1899, but was maintained throughout the eight years 1892 to 1899. Dr. Waldo has come to the conclusion that epidemic diarrhœa is due to the organic pollution of street-dust by horse dung and the consequent contamination of food by this dust when blown about. In country districts, he says, road-dust is practically free from horse dung and summer diarrhœa is hardly known. In the great majority of cases town children contract diarrhœa through the agency of milk, an obvious remedy for which state of things is to be found in the sterilisation of milk. Dr. Waldo also describes an interesting series of cases of typhus fever in which the disease was perpetuated at least from October, 1898, to February, 1899. The difficulties which arose in connexion with the former use of the crypt of St. George's parish church as a place of interment or deposit of bodies have now been overcome. By the end of 1899 upwards of 1400 bodies had been removed from the crypt and re-interred at Brookwood Cemetery, near Woking, the crypt being thereby cleared down to the floor level, which was afterwards cemented. As the parish of St. George-the-Martyr is now merged in the new borough of Southwark, the present report is the last one which Dr. Waldo will make to the vestry.

THE ESTABLISHMENT OF SANATORIA FOR PHTHISICAL PATIENTS.

THE scope of preventive medicine is widening day by day, and there are indications that in the near future diseases which are at present, in so far at least as practice is concerned, outside its limits will be brought within its sphere of active influence. For the moment attention is being turned prominently towards tuberculosis and the next 12 months are likely to witness some very material progress in this direction. In the annual report of almost every medical officer of health throughout the country the importance of this matter is accentuated, and although there is almost unanimous testimony against the compulsory notification of this disease there is an equally unanimous feeling that much may be done by proper preventive measures. County councils are, we are glad to see, taking a share in the work, and the county medical officer of health of Lancashire has recently issued a report upon the subject. In this report Mr. Edward Sergeant points out that during 1899 there were 2305 deaths from phthisis in Lancashire, and giving an average duration of three years to each case of phthisis he concludes that there may be some 6000 or 7000 phthisical persons living in the county, irrespectively, of course, of unrecognised cases The extent to which these unrecognised cases may prevail is illustrated by the fact that of the adult bodies examined after death some 38 per cent, according to the investigations of Dr. Thomas Harris of Manchester, show signs of healed tuberculosis of the lungs. Mr. Sergeant also refers briefly to sanatoria in several parts of Europe and to the testimony of experience to the effect that by treatment in well-managed sanatoria from 25 to 50 per cent. of the patients can be cured or more or less benefited. From these premisses he deduces that if the phthisis mortality in Lancashire could be reduced even by 25 per cent some 500 lives would be annually saved, and placing a pecuniary estimate of £159 upon each life, he shows that by this means alone about £75,000 per annum might be saved. In connexion with this question of sanatoria Mr. Sergeant refers to the law in force in Germany for effecting insurance against old age and sickness—a law which, he thinks, has not been without a material influence in bringing about the foundation of certain sanatoria, in the year 1898 from 3,000,000 to 4,000,000 marks being set aside by 33 societies towards the provision of such institutions. The key to the position may, indeed, perhaps be found in the fact that "half of the applications for sick pay between the ages of 20 and 29 among the insuring classes of Germany are because of tuberculosis." Finally, Mr. Sergeant raises the point, which we may consider subsequently in the columns of THE LANCET, as to whether sanitary authorities have power under the Public Health Act, 1875, to provide sanatoria, or whether the Isolation Hospitals Act, 1893, affords similar powers to county councils.

THE ADMINISTRATION OF THE OATH IN ENGLAND.

IT was to Mr. W. P Sinclair of Liverpool, whose death was recently announced, that we are indebted for the fifth section of the Oaths Act, 1888 (51 & 52 Vict. cap 46). The deceased gentleman represented Falkirk in the House of Commons, and when in 1888 the late Mr Bradlaugh brought in an Act to amend the law as to oaths Mr. Sinclair obtained permission to introduce the now famous section. As a Scotchman and a Presbyterian he, with many others of his fellow-countrymen and co religionists, was naturally annoyed at being asked, every time that he claimed to be sworn with uplifted hand, if that was the form of oath binding on his conscience His attention had been called to the letters and articles published in THE LANCET during the year 1888 and previously and had he experienced any opposition to the fifth section he would have called the attention of his fellow-Members to the grave objections we had then urged against kissing the book, the mode of adjuration adopted in England and Wales and Ireland, but not in Scotland or in the Channel Islands where the uplifted right hand is the form. There was, however, no opposition, the section being passed as follows: "If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question." This not only relieved Scotchmen and Presbyterians from being asked any questions, but, as will be seen, though this is not yet generally known, it relieved any and every person taking an oath or swearing to an affidavit under any circumstances whatever from kissing any book, whether Gospels or Pentateuch. It was a melancholy illustration of the proverbial uncertainty of the law that this Act, and especially this section, should have been, for years after it became law, unknown to lawyers themselves. Medical and other witnesses were illegally and rudely denied their lawful claim to be sworn as the Act permitted them by magistrates and by legal (not medical) coroners, and it required a circular from Mr. Asquith, then Home Secretary, to bring these recalcitrant gentlemen to their senses and to their duties. As the House of Commons meets next week it seems fitting that the attention of its members, whose proceedings are considered to be a model for others to follow, should be called to the preferable mode of taking the oath. No doubt the grievance of kissing the book is little felt in the House of Commons, and especially in a new Parliament. The renovation of the legislative chamber comprises new wigs for the clerks at the table and probably it includes also an ample supply of new copies of the Gospels and of the Pentateuch. The Speaker, the first commoner in England, is the first to kiss probably an absolutely new book. The contrast between this and courts of law is manifest. Nevertheless, we would urge that the handling and kissing of a book in any assembly and under any circumstances is an uncleanly procedure. In a recent issue we felt it our duty to allude to the question of the communion cup as a possible means of infection. The danger of kissing the book in coroners', police, sessions, or assize courts is greatly accentuated by the fact that medical witnesses are asked to do this after the book has already been kissed by numberless witnesses of the lowest class, including from time to time some infected with loathsome diseases. This fact was recognised by Lord Justice Collins, who, when presiding at the Central Criminal Court, ordered a book to be destroyed after it had been kissed by a witness suffering from syphilis. We have frequently pointed out the dangers of the English mode of administration before and have urged the adoption of the Scotch form. We could add much in favour of the latter form on the grounds of greater impressiveness and more solemnity, but we must leave this to others.

FARQUHAR, NORTH, AND CO. v. LLOYD.

THE case of Farquhar, North, and Co. v. Lloyd, tried before Mr. Justice Wills, in which the plaintiffs obtained a verdict for £1900 damages against the *Daily Chronicle* for libel, illustrates somewhat forcibly the dangers which a newspaper may encounter if in the discharge of its duty to the public it reports legal proceedings and ventures in addition to comment upon them. The plaintiffs, being manufacturers of tinned provisions, had sold goods to a tradesman who had refused to pay for them, contending that they were defective and that had he sold them they would have proved dangerous to the public. He appears to have been successful upon these contentions on being sued in the county court for the price of the goods. The *Daily Chronicle* in dealing with the case must from the verdict of the jury be taken to have erred in its criticism, in that it suggested that the stock of the plaintiffs, beyond those articles sold to the retailer referred to, would be found in an equally defective and dangerous condition. This the *Daily Chronicle* presumably inferred, not only from the particular goods having been found to be unfit for consumption, but also from the attitude adopted by the plaintiffs in endeavouring to enforce payment for them by legal proceedings—a step which certainly lent colour to the suggestion that the goods were in their view fit for trade purposes, although they maintained that they would have exchanged the defective tins for sound ones had they been asked to do so. By what particular process the jury that tried the action for libel fixed upon £1900 as the sum due to the plaintiffs it is useless to inquire; they possibly thought that with the costs added the defendant newspaper would lose the round sum of £2000. Granting, however, that the article in question exceeded the limits of fair comment upon the proceedings in the county court, it appears to us that the damages were excessive. Damages so large could only have been awarded with justice where it was proved beyond doubt that damage approximating to the sum awarded was caused by the publication of the comments objected to, and not by the publication of the facts proved in the trial upon which comment was made, and which must have been reported in many newspapers besides the *Daily Chronicle*. The dangers arising to the poorer classes of the public from the sale of inefficiently preserved provisions are great and real. We ourselves frequently lay stress upon them, and it would be a matter of regret if the freedom of the press honestly to criticise and to censure were to be curtailed by the fear of a verdict for unreasonably large damages following the slightest error made in dispensing such censure and criticism. This is our view, and it is no answer to it to say that the proprietor makes a profit by the publication of the newspaper containing such criticism and censure and that he need not publish either the newspaper or the criticism unless he chooses. To deny that the newspaper proprietor or the newspaper writer has in any case a duty to the public, or that he ever aims at the fulfilment of that duty is to indulge in silly cynicism. Both have a duty, and if they go too far in performing it they must suffer. But it is to the public good that they should not be made to suffer unreasonably.

THE RULE OF THE PAVEMENT.

WEAK, nervous, and elderly people are often made very uncomfortable by the overcrowding of the London pavements in the more frequented parts, while busy men are driven to despair by the obstacles to direct walking. Of late the inconvenience experienced has been increased by the fact that the people of London are, on the whole, less orderly and well-mannered than those of a previous generation. The deterioration of public manners of the men, and especially of the boys, in the street is a subject of constant remark amongst those whose memory carries them back only 10 or 15 years. Formerly the observant Londoner on visiting a country town was often struck by the fact that in the provinces the people as a rule walked about without any regard to rule, and he noticed that although the pavements or "side-walks," to use a convenient Americanism, were less crowded there was much more trouble in avoiding collisions with foot-passengers than was the case at that time in any part of London. We regret to say that London is now as bad as, or worse than, any country town. The unwritten rule of the pavement—that a pedestrian should walk on the right side—is a most valuable one, and has not only convenience but some prestige of antiquity to support it. It does not, however, date back beyond the last century, and it is not, so far as we know, possible to determine the origin of the rule. It probably came slowly into general use in London. Dr. Johnson while at breakfast in the Highlands one morning told Boswell that when his mother lived in London there were two sets of people, "those who gave the wall and those who took it," and that when he returned from London to Lichfield his mother had asked him to which set he belonged. "Now it is fixed that every man keeps to the right," said Dr. Johnson, "or if one is taking the wall another yields it and it is never a dispute." This, according to Dr. Johnson, was the state of things in 1772. All well-behaved and peaceable people took the right side, but the rule was not absolutely established at that date, for some few people still "took the wall." Why it was a sign of pride and of a quarrelsome disposition to "take the wall" when to "go to the wall" was synonymous with misfortune is a question for philologists; we are concerned only to insist that in the present crowded state of the streets of London order and method should be duly observed by pedestrians. Even those who object to religious education ought if they be good citizens to discourage rowdyism, and the hustling on the pavements of some of the crowded streets of the metropolis is hardly to be differentiated from rowdyism. The rule of the pavement should be taught in the board schools and it would be by no means a bad test question to put to all candidates for the London School Board to ask them whether they are or are not in favour of such teaching.

SIR ARTHUR SULLIVAN.

MUSIC, in so far at any rate as it conduces to happiness, is a great therapeutic agent, so we make no apology for referring in these columns to the loss which British music has sustained by the death of Sir Arthur Sullivan. In serious music he sometimes rose to great heights, as witness the fine chorus in *The Golden Legend*, commencing "The night is calm and cloudless." But where he shone pre-eminent was in his faculty for writing really humorous music. Take for examples the delicious burlesque solemnity of the entry of the judge and the fugal chorus of jurymen, "He'll tell us how he came to be a judge," in *Trial by Jury*; the introduction of the opening notes of the great G minor fugue given to the bassoon in the Mikado's song concerning punishment; and Arac's Handelian *aria di bravura* about his armour in *Princess Ida*. Sullivan's orchestration was always fitting and appropriate, and although *Ivanhoe* was not a success yet it contained at least one gem, the song "O moon, thou art clad in silver," with its delicate accompaniment given to flutes and muted strings. He was many-sided: he could write a song (notably, "Orpheus with his lute"), he could write a madrigal, or, to be more accurate, we should say a ballet or Fa-La, he was unrivalled at a patter song, and the music to "When the night wind howls," in *Ruddygore*, was a *danse Maccabre* which made the hearer shudder. By his art he lightened many weary hours, and though his works live after him it is sad to think that the hand which wrote and the brain which conceived them are stilled.

THE DENTAL HOSPITAL OF LONDON.

THE subject uppermost in the minds of those who attended the annual dinner of the staff and past and present students of the Dental Hospital of London, which was held on Nov. 24th at the Hôtel Métropole, was the approaching completion of the new hospital in Leicester-square. The information afforded on this head by a trustee and vice president of the hospital, Mr. F. A. Bevan, was very encouraging. He had recently visited the premises and could assure the present students that in a few months they would be able to conduct their studies in a building worthy of the best traditions of the institution. The benefits which this charity has conferred on a needy public may be best realised from the statement made by Mr. F. G. Hallett that during the past year over 68 000 cases had been treated at the hospital at a cost of less than £3000 Further proof of the need of increasing the accommodation of the hospital and the school was afforded by the fact that the numbers of students entering for the hospital curriculum continued to increase. Last term a larger number of students had joined the school than had ever joined before. How the work was carried to the successful issue which the past history of the hospital had shown in the old utterly inadequate building was a matter of surprise to all concerned Mr. C. S. Tomes, F.R S, urged the students and all those present who were interested in the well-being of the institution and the success of the school not to relax their energies towards increasing the fund for the new premises so that there might be no feeling of anxiety as regards the financial situation. It was a gratifying feature of the subscription list that old students had rallied round their *alma mater* by giving substantially to this fund. It was abundant proof that they appreciated the educational value of the hospital. More money, however, was needed. The dinner was well attended, amongst those present being many representatives of the various London medical schools.

THE Queen has given to Sir William Mac Cormac, Bart, K.C.V.O., President of the Royal College of Surgeons of England, Her Majesty's Royal licence and authority to accept and to wear the Cross of Commander of the Legion of Honour, conferred upon him by the President of the French Republic in recognition of services which he rendered to the French wounded during the war of 1870–71, as well as to the International Medicine Congress held during the recent Paris Exhibition. Sir William Mac Cormac is to be congratulated on this most recent addition to his many honours, and doubtless this recognition of his services by the French Republic will be highly appreciated by him.

PROFESSOR W. H. CORFIELD'S Harveian Lectures on "Disease and Defective House Sanitation," of which translations into French and Hungarian have already been published by the Royal Society of Public Health of Belgium and the Hungarian Society of Public Health respectively, have now been translated into Italian by Dr. Soffantini of Milan, and are being published, with the illustrations, in *Il Monitore Tecnico*.

THE first annual dinner of the Otological Society of the United Kingdom will take place on Monday, Dec. 3rd, at 7 30 o'clock, at the Café Monico, Sir William B Dalby, the President, in the chair Amongst the guests expected are Sir Thomas Smith, Sir R Douglas Powell, Sir Felix Semon, Mr. T. Pridgin Teale, Dr. F. W. Pavy, Dr. T. Barlow, Mr. T. Bryant, Mr. W. Watson Cheyne, and Mr. H. T, Butlin.

To mark their esteem and personal appreciation of the late Mr. Thomas Cooke, F.R C.S. Eng., some of his friends and past pupils recently presented to Mrs. Cooke a portrait of her late husband, together with a piece of plate Dr. Dundas Grant was chairman of the committee, Dr. David Walsh acted as honorary treasurer, and Mr. Wyatt Wingrave was honorary secretary.

MR. HERBERT F. WATERHOUSE, F R C S Eng., has been appointed Dean to the Charing Cross Hospital Medical School, *vice* Dr. Montague Murray, whose term of office has expired

DURING the week ending Nov. 22nd there were 39 fresh cases of plague in Mauritius and 25 fatal cases, making the total of deaths from plague 33

H.R.H. the Princess Louise, Duchess of Argyll, has joined the committee of the Coal Smoke Abatement Society.

MEDICAL WOMEN IN HUNGARY.—A woman has for the first time been allowed to take a medical diploma in Hungary.

UNIVERSITY COLLEGE, BRISTOL.—The annual meeting of the governors of this college was held on Nov. 21st under the presidency of the Bishop of Hereford. The report, which showed a satisfactory year's work, stated that 542 students had attended the classes during the year and added that the council viewed with much satisfaction the amalgamation of the Bristol Royal Infirmary and the Bristol General Hospital for the purposes of clinical instruction —The new wing of the college, comprising a large hall, a library, a laboratory, and class rooms, was opened at the end of September. The total cost of the building was £7500, towards which £6000 have been subscribed —The University Entrance Scholarship of the value of £50 open to medical students has been awarded to Mr. Samuel C Hayman.

ARSENICAL POISONING FROM BEER-DRINKING.

Notes by T. N. KELYNACK, M D. VICT., M.R.C P. LOND.,
MEDICAL REGISTRAR (LATE PATHOLOGIST), MANCHESTER ROYAL INFIRMARY; ASSISTANT TO THE PROFESSOR OF MEDICINE, THE OWENS COLLEGE, HONORARY MEDICAL OFFICER, PENDLETON BRANCH OF THE SALFORD ROYAL INFIRMARY.

Analytical Report by WILLIAM KIRKBY, F.L.S.,
LECTURER ON PHARMACOGNOSY, THE OWENS COLLEGE, MANCHESTER.

Notes by PROFESSOR SHERIDAN DELÉPINE,
PROFESSOR OF PATHOLOGY IN VICTORIA UNIVERSITY (OWENS COLLEGE);

AND C. H. TATTERSALL, L R.C.P. LOND; M.R C.S. ENG.,
MEDICAL OFFICER OF HEALTH OF SALFORD.

FOR some time past the number of cases of "peripheral neuritis" in Manchester and Salford has been rapidly increasing, and recently they have reached "epidemic" proportions. This at first was not unnaturally thought by some to be due merely to increased drinking associated with the recent elections and rejoicings in connexion with the war. But soon it was found that not only were the cases extremely numerous but that they presented features unusual in so-called "alcoholic peripheral neuritis." Large numbers came under observation in the various union infirmaries and flooded the out-patient departments of the hospitals. For some time past I have been seeing many amongst the very poor people attending the out-patient department of the Salford Royal Hospital at Pendleton. Some few have also been under observation in the wards of the Manchester Royal Infirmary. The patients are generally "beer"-drinkers, although some admit partaking of spirits in addition. Both men and women are affected, the latter often suffering severely. I have seen no distinct cases in children, although large numbers of poor children have been attending our out-patient department at Pendleton.

Complaint.—In most instances the patients have sought assistance on account of the weakness and pains in the limbs. They describe their sensations as like "pins and needles," "numbness," "pricking," "like walking on hot bricks," or "scalding." Some complain chiefly of their difficulty in walking. In more advanced cases they declare themselves as "paralysed" and are quite unable to get about. In some few cases the pains are more general. One woman came complaining that she and her mother had "rheumatism all over." Many seek advice on account of the "rashes" and "itching" of the body, but generally the poorer patients affected have not been particularly observant of the pigmentation. In some persons, however, the increasing darkening of the skin has been the chief feature to attract notice. Not a few complain of "smarting of the eyes," "a cold in the head," "running of the eyes and nose," or even "influenza." One woman complained bitterly that her eyes were always "running and scalded her cheeks." Many have "gone hoarse." In some few cases a history of nausea and vomiting has been given. Not a few say that their hands and feet are getting thick "and the skin crumbling." Numerous cases have presented herpetic and other skin eruptions.

General aspect.—This in a well-marked case is very characteristic. Frequently, but by no means always, the appearance is "alcoholic." The face is usually dusky, the eyes watery, and often with tears visibly overflowing. Sometimes there is distinct puffiness about the eyelids. Walking is usually difficult and the patients progress in a gingerly or ataxic manner. In bad cases there is much general wasting. The temperature in severe cases may be raised. In an affected district one can readily recognise the subjects of this remarkable malady from their tearful expression as they stand at their doors or shuffle about the house and loiter at street corners.

Cutaneous system.—In almost every case the skin is more or less involved. 1. Pigmentation is the most conspicuous feature. This may be general. It varies greatly in intensity in different parts of the body. As in Addison's disease, it is frequently most marked on exposed parts, over pressure areas, and in the normally pigmented situations. In tint it often resembles a "vagabond pigmentation," and has, I believe, not infrequently been put down to "dirt." One of the sisters in the infirmary tells me that one patient on admission was washed three times without visible improvement. Many of the female patients have been much disconcerted at their growing duskiness. The pigmentation varies from a mere "browning," as from exposure to sun, to an almost dull black in pigmented regions, like the areola. In many the distribution is irregular. The face is often comparatively slightly involved. I have, however, seen very dark pigmentation of the eyelids. The neck is often very brown. The pigmentation is usually best marked in the axillæ, groins, areola, and abdominal wall. It is frequently intense around the umbilicus. Scars and old cicatrices are usually non-pigmented. The appearance of the skin is often curious; numerous very small round islands of skin but little pigmented may be seen in the midst of the deeply-pigmented areas, giving the body a "spotted" appearance. It is well, however, to point out that in many of the very marked "neuritic" cases the pigmentation is so slight as to be readily overlooked. 2. Herpes has been met with in a large number of cases. Dr. R Forsyth and Dr. Hitchon, medical officer of health for Heywood, tell me that they have had quite an "epidemic" of herpes in their practice. 3. Erythematous eruptions have been present in a large number of the cases. 4. A papular eruption has also been common and usually associated with much itching and discomfort. 5. In many a "branny" desquamation can be observed. The shed epithelium may be pigmented. I have seen it so plentiful as to give rise to a conspicuous deposit on the bed-sheet. One woman I saw at Heywood with Dr. Hitchon complained to me of the "crumbling away" of dirty skin from her chest. The same patient said that her hands were so hard and cracked that she found it impossible to keep them clean. 6. The cuticle becomes thickened, especially in the hands and feet. Many have particularly complained to me of this. Some have found that their hands get so "thick" that they cannot well close them The thickening is generally most marked over the heels and balls of the toes, but the hands are also frequently much affected, especially over the thenar and hypothenar eminences and around the knuckles. In some cases the thickening of the hands may be general. Patients have spoken to me of the way in which they have detached the thickened skin from their feet. When they continued to walk about I have observed distinct "blisters" in the areas of keratosis. 7. The nails become hard, thick, and brittle, and one man tells me the nail "came off by itself." Some patients have remarked that the nails grow with unaccustomed rapidity and the cutting of them is very difficult. I have not observed any very marked change in the hair. 8. Boils have been met with in such situations as the vulva.

Nervous system.—Sensory symptoms of almost every degree are marked in practically every case. These vary, ranging from slight numbness to the most intense pain. Patients often dread to be touched and sometimes cannot bear even a sheet to rest on the feet. Cramps may be severe. Curiously enough, the chief sensory disturbances are generally limited to the extremities well below the knees and elbows. In not a few cases I have found the patients limiting the area of pain and discomfort to the hands and feet. Sometimes a slight movement of the leg or jar to the bedstead will make the patient cry out in anguish, the pain shooting upwards along the nerve-trunk, and, from the description given by the sufferer, seeming to resemble closely the shooting pains in "locomotor ataxia." In some cases the patient has been thought to be suffering from "sciatica." Occasionally the pain and anguish may be intense. When visiting some of the cases with the medical officer of health of Heywood I found one poor woman in such agony that her medical attendant had been obliged to administer morphia. I have seen many cases in which the area of the pain and character and distribution of the erythema in the feet closely resembled the affection termed "erythromelalgia." In many the border of the erythematous portions has been more or less clearly defined and usually running along the borders of the feet. Sweating has often been well marked, but is by no means constant. The degree of motor involvement varies greatly. Some patients insist on moving about, although often with a shuffling, unsteady gait. They readily get tired and stop to rest, leaning for support on anything convenient. When sitting down many reach their chair with a "flop," and in rising are obliged to assist themselves with their hands. Tremors are often present and are evidently not always due to the alcohol. The ocular muscles are apparently not affected, and so far I have not met with any distinct case of paralysis of the intercostal muscles and diaphragm. Manifestations of trophic disturbance are present in all cases. The reflexes vary considerably. The superficial reflexes are often exaggerated even in long-standing cases. The "knee-jerk" is diminished or abolished in the greater number of cases, but I have met with it distinctly increased in severe cases. Hitherto I have not been able to take the electric reactions. Although mental derangement has been met with in many cases these have generally been in the excessive drinkers and it has been more or less of the usual "alcoholic" character, and in some of the cases cerebral disturbance has been apparent.

Respiratory system.—The mucous membrane of the respiratory passages is much congested in many cases. If the nose is not found "running" usually moisture from serous discharge will be seen immediately within the nostrils. The "catarrh" often involves the larynx, and very many of my patients have complained of "huskiness" and alteration in their voice. In some few it has been so marked that the patients could only phonate with difficulty. The lungs apparently do not suffer directly, at least to any extent, but I believe it will be found that some deaths have occurred from respiratory failure due to paralysis of the diaphragm.

Circulatory system.—Some of the beer-drinkers present the usual evidence of cardiac enlargement and muscle failure, but in the cases arising in strictly moderate indulgers there seems to have been no direct action on the circulatory apparatus. It is important to bear in mind, however, that the irritant may be capable of setting up "neuritis" of the vagus.

Digestive system.—The tongue is often "furred" and in some instances presents an appearance best described as "silvery." The mucous membrane of the mouth is not pigmented. In mild cases the appetite may be fairly good. I have not met with true ulceration of the gums or fauces. There may be slight catarrh of the pharynx. Salivation has not been marked in the cases I have seen. Nausea and sickness are present in not a few, but I have been surprised to find that many severe cases have never had any vomiting. Diarrhœa is exceptional; many cases are constipated. Colic is practically never complained of, but some have experienced epigastric pain and slight general abdominal discomfort.

Urinary system.—This presents but little evidence of derangement. One man complained of some "smarting" during micturition, and some have said that they passed urine more frequently. In severe cases the urine may be high-coloured. Generally no important alteration in the urinary secretion has been noticed. We hope to be in a position at a later date to give the results of our investigations regarding the urine.

Clinical varieties.—From a study of the clinical cases it is easy to distinguish two chief groups: (1) those which were manifestly "alcoholic," and (2) those which both from a consideration of their history and from their general appearance were manifestly not excessive indulgers in alcoholic drinks. Not a few of the cases, I am convinced, belong to this group. Among the sufferers in the Heywood outbreak I saw several. One was a young woman who had taken "stout" for many years, about a pint daily. There were no reasons to believe that she was in any way to be considered intemperate. She had certainly been "affected" for six months by the prevailing malady, although not in a severe form. In a later communication I hope to deal with the special clinical types.

Nature of the poison.—For long these cases have been looked upon as simply "alcoholic multiple neuritis." Later it became manifest that it was of an altogether exceptional type, and then it was realised that this was almost certainly due to some special irritant or irritants in the liquors taken. Finally, Dr. E. S. Reynolds, assistant physician to the Manchester Royal Infirmary and visiting physician to the Manchester Union Hospital, made the startling discovery that arsenic existed in the beer. This fact was announced to the profession at the meeting of the Manchester Medical Society on Nov. 21st, and the public first learnt of it from the newspapers of Nov. 23rd.

Duration of the malady.—It is very difficult at present to ascertain how long this arsenical poisoning has been going on. Probably for very many months. Certainly it has existed in this district in "epidemic" form for at least two months. Many of my Salford cases date their symptoms back for about nine or ten weeks. On Nov. 12th I saw in consultation with Dr. J. W. Crawshaw of Weaste a very marked case where the patient, an intelligent woman, aged 39 years, dated the commencement of her pigmentation, which was intense when I saw her, to June, which time she was able to locate exactly, as she was at the Isle of Man from June 1st to 9th, and observed the brown discolouration starting on the left side of her neck a week after her return. Dr. Crawshaw writes to me to the effect that "for some time before she went away she had noticed a troublesome watery discharge from the eyes and nose." We may therefore, I think, conclude that this form of poisoning has been going on for at least six months. It was remarkable that the cases generally occurred in "beer"-drinkers. In Heywood, however, consumers of "stout" have also been affected. The poorer classes have been the chief sufferers. Generally they have owned to taking "fourpenny beer," but some have taken "sixpenny" and others "bottled beer." Salford has suffered severely, while some districts of Manchester, so far as I can at present ascertain, have been hardly affected. But the cases are by no means limited to Manchester and Salford. Those I have seen in Liverpool, Heywood, and Warrington are similar to those in Manchester and immediate district. Our researches go to show that many of the important large towns in the district are affected, and even the villages would seem not to have escaped. This fact has made us most desirous of placing the results of our investigations before the profession, so that steps may be immediately taken throughout the country to insure that the painful experience of Manchester may not be repeated elsewhere.

Localising the source of the arsenic.—Directly the cause of the poisoning became apparent I immediately sought the coöperation of Mr. Kirkby, of the Pharmaceutical Department of The Owens College, and Dr. R. Forsyth, medical officer to one of the largest firms of brewers in Salford. We have the satisfaction of knowing that as the result of our labours the source of the introduction of the arsenic into the "beers" was localised within a few hours of the announcement of the nature of the poison to the public, and early on Nov. 23rd we informed the medical authorities of Manchester and Salford and the brewers themselves of our discovery, and also Dr. Dreschfeld, senior physician to the Manchester Royal Infirmary. Dr. Forsyth has rendered us invaluable help and the brewers have afforded every facility for the investigation of all the materials used by them in the making of the affected "beer." We have also received much assistance from Dr. Harold Bailey who has obtained samples of the "beer" taken by many of the affected patients.

Treatment.—A word or two of caution and suggestion may be added in regard to the treatment of the sufferers. Now that the nature and source of the irritant has been ascertained it may be hoped that all necessary steps will be taken to arrest the "malady." Affected cases will, however, for some time to come call for careful management. In every case it will, of course, be found necessary absolutely to forbid the use of all drinks which may be suspected to contain arsenic. I also believe it will be found best to withhold every form of "spirit." Rest must at once be enforced and severe cases sent to bed. I know from what I have myself seen that many are now aggravating their sufferings and lengthening their illness by neglecting to insure rest for the affected tissues. Immediate steps should be taken to provide for the poor sufferers an adequate number of nurses in towns where these cases have occurred, and especially in those places where unfortunately no hospital is at present available. For many of the cases it will be desirable to arrange for a long course of massage. A recently published treatise on medical treatment states that for "alcoholic neuritis preparations of arsenic are sometimes valuable." It is to be hoped that this suggestion is not being acted upon with regard to any of the cases now under consideration. Realising the far-reaching importance of the subject we have felt it to be our duty to the profession and to the public to publish our results at the earliest possible moment, but we hope to be able to deal with certain further matters of much scientific and medico-legal importance in a subsequent communication

Report on Beers and Brewing Sugars implicated in the Outbreak of Arsenical Poisoning in Manchester and Salford.

With a view to elucidate the mystery concerning the epidemic of arsenical poisoning in Manchester and Salford Dr. T. N. Kelynack obtained for me samples of beer which was habitually drunk by five patients under observation, the said samples being bought by the patients themselves or by their relatives under the direction of a medical man. There was no difficulty in detecting arsenic in these samples. Through the kindness of Dr. Forsyth and of one of the largest and most influential brewers in the district Dr. Kelynack obtained three samples of beer bottled in August, October, and November. In these also arsenic was found in varying proportions. Having ascertained (*a*) that the people under treatment were drinking beer contaminated with arsenic, and (*b*) that the beer was actually leaving the brewery with the arsenic in it, it was clear that all possible sources of contamination between the brewery and the consumer could be safely ignored. A brief review of the known constituents of this beverage indicated that the most probable source of the poison would be found in some article in the production of which sulphuric acid is used, as this frequently contains arsenic as an impurity. I accordingly asked for, and was most courteously supplied with, samples of calcium sulphate (used for water hardening) and "invert sugar." The first of these was quite pure, but the second was charged with considerable quantities of arsenic. Immediately upon ascertaining this (the morning of Friday, Nov. 23rd) Dr. Kelynack was informed and he at once communicated the intelligence to the medical officers of health for Manchester and Salford and to the brewers concerned.

Immediately upon the fact becoming known another very prominent firm of brewers came to my assistance, and with the combined help of them, Dr. Forsyth, Dr. Harold Bailey, Dr. Crawshaw, and others Dr. Kelynack and I are now able to publish the subjoined lists of figures which at present require no comment from a chemical point of view. It should, of course, be distinctly understood that in determining such minute quantities of arsenic the figures can at the best be approximations to the truth. Every figure, however, is the outcome of at least three experiments and in many cases of six experimentt. The quantities are given in terms of arsenious acid (As_4O_6) because the dose of this is probably the most familiar to practitioners.

Beers, &c.

1	Beer	From patient	0 14 grain per gallon.

17	,,	,, ,,	0·20 ,, ,,

The above beers, &c., were examined because they were suspected. Now, however, we are turning our attention to the beers which are being sold from day to day, and concerning these we shall report in the near future.

Brewing Sugars.

1.	Invert sugar	3 parts in 10,000 parts.
2	Invert sugar	3 parts in 10,000 parts.
3.	Invert sugar	Nil.
4.	Glucose	4 parts in 10,000 parts.
5	Glucose	Faintest trace.
6.	Glucose	Faintest trace.

I have the best reason for believing that Nos. 1, 2, and 4 have a common origin.

That arsenical impurity should result from the employment of sulphuric acid in the manufacture of these sugars is not greatly to be wondered at when it is remembered that the greater proportion of the acid is obtained from iron pyrites. But the recurrence of such a sad state of things as now exists in this district must be obviated in the future by the establishment of a test for arsenic to which all sulphuric acid that is to be used for the manufacture of food and drinks must conform, just as in the case of that which is used in medicine.

I must tender my thanks to Mr. Roy for his assistance, and to Messrs. Jewsbury and Brown for the use of their laboratories and for other facilities afforded me in prosecuting these investigations.

WILLIAM KIRKBY, F L S.,
Pharmaceutical Chemist; Lecturer in Pharmacognosy in the Owens College.
Manchester, Nov. 27th, 1900.

NOTES ON RECENT BEER POISONING IN SALFORD, WITH A TABLE OF ANALYSES.

On Nov. 9th Mr. R. D. Cran, the Poor-law medical officer of the Regent District of Salford, reported a large amount of illness of a paralytic nature in his practice which he had concluded was due to beer-drinking. On that day five samples of beer were obtained and forwarded to the public analyst and a further ten samples a few days later. He, however, failed to find anything to account for the illness. It had been noticed for some time that deaths from "peripheral neuritis," "multiple neuritis," and "alcoholic neuritis" were more numerous than usual and inquiries had been made among a few friends who had not noticed any excess in illness of this character in their practice.

The increase in deaths from this cause commenced in the third week in July, from which time to the present the weekly figures have been: 3, 0, 1, 1, 1, 2, 2, 1, 2, 4, 2, 1, 2, 3, 3, 4, 5, 2, and 2, making a total of 41. In addition, during the same period there were 25 deaths certified to be due to "alcoholism," or a total of 66 in the past four months, as compared with 22 in the first seven months of the year, 39 in 1899, 31 in 1898, and 27 in 1897.

Immediately following Mr. Cran's notification an inquiry was commenced into the circumstances of all the cases that could be heard of, and it was soon abundantly clear that the one thing common to all was beer-drinking—not necessarily to excess—and it was further ascertained that the cases were not confined to the drinkers of beer from one particular brewery.

On Nov. 16th we consulted together and concluded that the only probable causes of the peculiar sickness were: (*a*) metallic poisoning (lead or arsenic); (*b*) poisoning by higher alcohols accidentally present in the beer; and (*c*) poisoning by some unknown bacterial product. Samples of beer were obtained on Nov. 19th from a shop to which one case of illness could be clearly traced for purposes of experimental investigation.

On Nov. 20th we heard that Dr. E. S. Reynolds had found arsenic in a sample of beer and that his observation had been confirmed by Professor J. Dixon Mann, and we had no difficulty in satisfying ourselves of the presence of arsenic in our samples. Specimens of every article used in the brewery concerned were obtained and examined, arsenic being found in one sample of glucose (out of three) and in a sample of inverted sugar on Nov. 22nd. It was ascertained that both these substances were purchased from the same firm of sugar manufacturers. Their works were visited on the 23rd and samples of everything used were examined, and it was found that the only sulphuric acid used was loaded with arsenic. The sulphuric works were visited on the 24th and it was ascertained that the sulphuric acid was the ordinary commercial sulphuric acid prepared from arsenical pyrites. In all 62 samples of various kinds were examined for the presence of arsenic; the portions of these analyses are given in the accompanying table. The results show that there is no arsenic present in any substance which cannot be traced to the use of this impure sulphuric acid by this particular firm.[1]

Professor Harold Dixon, F.R.S., of the Owens College, has made an examination of the sulphuric acid, glucose, and beer, and he reports as follows: "The sulphuric acid was found to be highly contaminated with arsenic. I can say with certainty that it contains more than 1·4 per cent. by weight of arsenious acid. The glucose contains a very considerable quantity of arsenic. Owing to the limited time at my disposal I am not prepared to speak with the same certainty as to the exact percentage of arsenic present, but there is strong evidence that this glucose contains fully 0·5 per cent by weight of arsenious acid The quantity of arsenic in the beer is small and it would require a considerable time to make a quantitative analysis, about the presence of arsenic in appreciable quantity there can be no doubt"

---

[1] Although immediately after hearing of the discovery of arsenic by Dr. Reynolds we suspected for obvious reasons brewers' sugar as the source of arsenic we thought it necessary to continue our investigation of all the ingredients entering into the composition of beer. We had not only to prove the presence of arsenic in sugar, but also to prove its absence in all the other articles. In addition to this we took steps to ascertain the exact amount of arsenic present in certain samples of beer and in the corresponding samples of glucose and sulphuric acid, in order to satisfy ourselves that there was enough arsenic in the sulphuric acid to account for the whole mischief. In Mr. Wynter Blyth's book on "Foods, their Composition and Analysis," fourth edition, p. 542, the results of analyses of arsenical glucose by Ritter, and by Clonet ("Annales d'Hygiène Publique," xlix., January, 1878) will be found. Our results do not agree with those of Ritter, for we found a large amount of arsenic in some of the whitest glucose.

Table of Analyses.

No	Material	Arsenic.	No	Material	Arsenic.
	Firm A			*Firm D*	
α	Beer	+	2	Hops	–
β	"	+	3	"	–

29	"	–		*Various other beers*	
30	"	–	I	—	–
31	"	–	II	—	–
32	"	–	III	—	–
33	"	–			
34	"	–		*Firm F, Brewers' sugar manufacturers from whom sugars used by Firm A and E are obtained*	
36	Preservative.	–			
35	Gypsum	–			
27	Water	–	44	Glucose	+
	Firm B		45	—	+
13	Hops	–	46	—	+
14	"	–	47	—	+
15	"	–	48	—	+
16	"	–	49	—	+
17	"	–	50	Inverted sugar	+
18	"	–	51	"	+
19	"	–	42	Sulphuric acid	+++
20	"	–	43	Sulphurous acid	–
38	Glucose	–	56	Whiting	–
39	"	–	52	Maize meal	–
	Firm C.		53	Sago flour	–
1	Hops	–	54	Tapioca flour	–
37	Glucose	–	55	Cane sugar	–

From these results it is evident that arsenic is contained in the beer in sufficient quantities to account for chronic arsenical poisoning The symptoms of the cases inquired into are also quite consistent with this view—viz, running of the eyes and the nose, pigmentation of the skin various rashes, including peeling of the hands and feet, paralysis, analgesia myalgia, pins and needles in the hands and feet, and diarrhœa (in one case) Other cases have been heard of where the individual has suffered from vomiting and diarrhœa and has at once ceased drinking the offending beer, no further symptoms occurring Further, every case we have followed up (about 100) can be traced to beer in the brewing of which glucose or sugar from one manufactory were used As this firm supply about 200 breweries, to a greater or less extent, in the North of England and the Midlands, it is not surprising to find that similar cases of illness are occurring in other districts

It is due to the sugar manufacturers to say that we understand they have issued a circular to their customers advising them of the facts and requesting them not to use any of the materials already supplied Our thanks are due to the brewers for the facilities which they have given for the prosecution of our inquiry, and there cannot be the slightest doubt that they are entirely innocent of any negligence

We cannot conclude without referring to the very great assistance which we have received from Dr Coutts, F I C, who has carried out the great bulk of the analyses In conclusion, we think we have proved the correctness of Dr Reynolds's opinion that this outbreak of disease is due to arsenical poisoning from beer drinking, that the presence of arsenic in the beer is due to the use of contaminated glucose and inverted sugar by the brewers; and that this contamination of sugar is caused by the use of very impure sulphur acid by the sugar manufacturer prepared from arsenical pyrites It seems to us very necessary that the use of sulphuric acid in the preparation of articles for consumption should be placed under strict supervision

SHERIDAN DELEPINE
Salford, Nov 27th 1900 O H TATTERSALL

*** We have received photographs of the octahedral crystals of arsenious acid obtained from 40 cubic centimetres of the specimen of beer marked γ in the table, and from three grammes of the specimen of glucose marked 44 —ED L

THE NEW PROPHYLAXIS AGAINST MALARIA. AN ACCOUNT OF EXPERIMENTS IN LATIUM

BY PROFESSOR ANGELO CELLI

(*Specially translated for* THE LANCET *from the Supplemento al Policlinico, Anno VI, N 51*)

THE modern theory of the propagation of malaria by means of mosquitoes had scarcely been confirmed experimentally when, in my lectures in May and June of 1899 and shortly afterwards in book form[1] I gave an exposition of the new epidemiology and the prophylaxis following from it This, I pointed out in order to be completely successful must be directed against (1) the causes bringing about infection, either by (*a*) destroying these (by disinfection of the blood of malarious persons and by the destruction of mosquitoes) or (*b*) by preventing their entrance into the human organism (by protection of dwelling houses and of the exposed parts of the body); and (2) against the predisposing causes (organic, physical, and social) In view of the arduous nature of any attempt to battle against the latter set of causes I endeavoured (even before the commencement of the malarial season of 1899) to put into practice those only of the prophylactic measures which have for their aim the suppression of the direct causes of the epidemic that is to say, the causes bringing about infection I was even then persuaded, and am now more than ever convinced, that a complete and certain prophylaxis by disinfection of the blood by means of quinine is practically impossible, although Koch, and later Gosio, and at first Grassi also, believed in its efficacy. And I had likewise come to the conclusion, through my own and Casagrandi's researches,[2] that although the destruction of the mosquito in the aquatic and the aerial stages of its existence is in itself not a difficult thing, this is not practicable on a large scale, chiefly because there is not the same immediate material advantage in killing insects which are injurious to man that there is in destroying those which are injurious, for example to the grape vine

My first prophylactic experiments of 1899 had consequently for their object the testing of the means best adapted to prevent the bites of mosquitoes and the resulting penetration of the malarial germ into our bodies On one hand I made experiments with various substances, such as ointments soaps, and odours calculated to drive away mosquitoes, and satisfied myself that they were of little use, even the best of them, as, for instance, those with turpentine for their basis, either because of their ephemeral effect, especially in the open air, or because of the negligence of those employing them On the other hand, I adopted the method of mechanical protection of the houses and of the exposed parts of the body, not omitting at the same time the disinfection of the blood by an assiduous attention both to relapses and to primary fevers, and the destruction of any mosquitoes which might accidentally penetrate into the houses. It will be well to refer here once more to the experiment which I made in the æstivo-autumnal season of 1899 on the two railway lines, notoriously malarious, of Prenestina-Cervara and of Pontegalera. I shall therefore give a brief *résumé* of the official report dated Dec. 13th of last year.[3] On the first-mentioned of these two lines we selected for experiment the linemen's cottages numbered 4, 5, 6, 7, and 8, and on the second those numbered 19, 20, and 21. We covered the windows with frames of tulle,[4] thus allowing air and light, but no mosquitoes to pass. At the top of the staircase a door with a similar frame was placed the better to protect the bedrooms. This door, as well as the outer ones, was made to close automatically so as not to demand too much of human apathy. The entrance door, as being more liable to injury, was furnished with wire gauze instead of muslin. We advised the inmates to sleep with the windows open so that the air, filtered as it were from insects, might pass in freely. For the protection of persons employed on night duty we used cowls like those of bee-keepers, provided with a circular mask of wire gauze and having attached to it below a veil tucked under the coat, at the ends of the sleeves of which very wide gloves of chamois skin were tightly sewn on. A vigilant outlook was daily kept for mosquitoes in order to find and eventually to capture them in the houses. Every family was provided with a powder for burning in case by any chance a mosquito should make its way in The neighbouring linemen's cottages and the stations of Cervara and Pontegalera served as controls. On the Prenestina-Cervara line Cottage No. 6 served the same purpose, the inmates being negligent and refractory and allowing mosquitoes to enter constantly. Some of the latter were found infected so that we were able to predict the epidemic which afterwards developed attacking 12 out of the 14 inhabitants. Among the controls on the Cervara line 24 persons contracted malaria and at the station of Cervara, renowned for its malaria, all were attacked. In the control zone of Pontegalera, two persons who had acquired immunity from having had the disease previously escaped infection. On the other hand, in the linemen's cottages which were protected, out of 24 persons four were attacked, but these were on night duty and took no heed of our instructions. Three of them were ill for a long time, two from tertian, spring and autumn varieties respectively, and one from quartan fever. In spite of quinine administered promptly and abundantly they relapsed several times and their blood contained a large number of gametes—that is to say, of those parasitic forms most dangerous for contagion. At the same time their wives and children living in the protected houses along with them enjoyed immunity from the fever. The disease did not therefore spread through a whole household in the usual way, and *for the first time since the construction of these lines of railway the families of the railway servants were able in highly malarious localities to pass the whole summer and autumn in the Campagna without contracting fever.*[5]

[1] Malaria According to the New Researches (Longmans Green, and Co.)

[2] Per la Distruzione delle Zanzare, Mem I Annali d Igiene Sperimentale, vol ix, 1899

The result of these experiments, which were the first of their kind in malarial districts, very greatly impressed Manson,[6] who came to see my field of experiments at Cervara,[7] and they induced the directorate of the Adriatic Railway Company to extend the system in Latium from Prenestina to Salone and on the Castelgiubileo line; and also into Southern Italy near the station of Ofantino in the Province of Foggia.[8] The Southern Railways Company in its turn determined to extend the same experiments to the most malarious of the linemen's cottages on the lines of Terracina, Anzio, and Pontegalera, here in Latium, and to those near the station of Albanella in the province of Salerno. The conduct of the former of these two experiments was entrusted to me, the other, in Southern Italy, to Grassi, who was member of a consultative committee appointed for the purpose by the same railway company.[9] In like manner the Sicilian railways have also extended to the sections of their lines lying in malarial zones the same system of prevention. I must, however, limit myself to an account of the results of the new prophylaxis as obtained in Latium, where, encouraged and taught by the experience of last year, I attempted to defend against malaria in the season which is now drawing to a close, not only the railway servants, but also the caretakers in the Campagna and the peasants. I shall now briefly recount what I did for each of these and the results which I obtained.

A.—PROTECTION OF THE RAILWAY SERVANTS.

The method employed was that of the previous year, with the difference that wire-gauze[10] was everywhere substituted for the muslin, and that a large cage of wire-gauze was placed in front of the door so as to form a kind of porch or ante-chamber. This addition of a porch, first suggested by Dr. Blessich, is very useful in giving greater protection to the rooms on the ground floor and affording a shelter where in the summer the family can have the benefit of the open air without actually going outside. As a rule, the doors were made to close automatically, and to make sure that no mosquitoes entered by the chimneys the latter were also covered by gauze with a wider mesh. To render easier the discovery and destruction of any mosquitoes that might chance to enter, the walls of the rooms were whitewashed.

Large and repeated doses of quinine had been administered to any persons who had had relapses in the spring as well as to the very few patients with primary infections, the treatment being completed in all cases with arsenical and ferruginous preparations. No prophylactic medicine was given except to those on night duty on the Adriatic lines, whom I had not been able to induce the previous year to wear regularly at night time the special head-gear and gloves provided for the purpose. They were made to take euchinin in a daily dose of from 0·50 to 0·75 centigramme. On the Mediterranean lines we had not the same difficulty, because there mosquitoes and other insects are so numerous as to cause intolerable annoyance, apart from any danger of their conveying fever. The results which we obtained were briefly as follow.

1. Prenestina-Salone line. On this line we this year protected also the houses on the Cervara-Salone section which last year served us as controls. We were able, however, to use for this latter purpose the intermediate stations of Cervara and Salone as well as the section beyond from Salone to Lunghezza. Now in the zone which was protected out of 52 persons only two contracted fever—namely, a watchman on night duty attacked on June 15th (before the commencement of the prophylactic treatment of those engaged in this dangerous service) and a woman attacked on Oct. 15th who had always shown herself refractory to our recommendations. The watchman, notwithstanding abundant and repeated doses of quinine, had had three relapses at long intervals; nevertheless, his malaria did not prove infectious to the other seven persons who lived in the same house. In the rest of the protected zone 50 persons (21 adults and 29 children) remained free from fever. On the other hand, in the zone of control, two out of three persons sickened at the station of Cervara, 16 out of 18 on the Salone Lunghezza section, six out of 10 in the station of Salone—the four who escaped having been in the habit of frequently sleeping at Rome—and in the houses of the country people along the protected portion of the line and in the huts of Salone there were about 100 peasants, all of whom sickened. Also on the farms of Rustica, Cervelletta, Bocca di Leone, and Gottifredi all, or nearly all, took the fever. *Our protected zone thus remained almost free from malaria in the midst of a fever-stricken region, and in order to render healthy a district where during the preceding year*

---

[4] These frames were never removed from the windows of the first floor of cottage No 19 on the Pontegalera line and now, two years later, are still in excellent preservation. For those who cannot afford metallic frames the muslin ones may be recommended.

[5] Vide Bollettino n. 3 della Società per gli Studi della Malaria. Sitting of Feb. 5th, 1900.

[6] Brit. Med. Jour., Feb 10th, 1900.

[7] A very pleasing sequel to this visit was the experiment of Dr. Sambon and Dr. Low who, in order to obtain documentary evidence as it were of the efficacy of the new prophylaxis, came and passed the malarial season in the most deadly spot in Ostia in a hut protected against mosquitoes and who, together with two other persons, have remained all the time in perfect health.

[8] Dr. Martirano, who has carried out the prophylactic experiments at Ofantino on 28 persons, has not had a single case of primary malarial infection to report.

[9] Professor Grassi published before the season had come to an end an anticipatory report, and this without any hint that others had been working before and were still at work for the railway company and for the Society for the Study of Malaria, by whom the funds were supplied.

[10] The diameter of the mesh of the gauze should not be greater than two millimetres at most; this size prevents the entrance of any but a very small culex. To exclude all sizes of mosquitoes with certainty the mesh should have a diameter of only from 1 to 1·5 millimetres. A coat of varnish is applied to preserve the netting.

everyone had had fever it sufficed to extend to it the new method of prophylaxis

2 Castelgiubileo line (from the seventh to the nineteenth kilometre inclusive) On this line the experiment succeeded in a degree highly convincing Here there are two types of lineman's cottage—the new and the old, the latter from its peculiar construction does not lend itself to being protected and was therefore left to serve the purpose of control This turned out to be a fortunate circumstance because the old and the new cottages as nearly as possible alternate with one another Now in the protected houses out of 57 inhabitants not one took fever, while in the unprotected houses out of 51 inhabitants only seven escaped, and these were nearly all adults, immune in consequence of previous attacks Among the children, on the other hand, only two out of 29 escaped infection in the unprotected huts whilst of the 36 children in the protected houses not one was attacked We also made two further control experiments On August 23rd it became necessary, for reasons connected with the railway service, to transfer a family consisting of a husband, wife, and son from cottage No 17, where they had always enjoyed good health, to the next cottage, No 16 About a month afterwards the wife and child were attacked by fever On the other hand, a family consisting of husband, wife, and six children, all of them suffering from malaria, had been placed in cottage No. 17 We at once put them upon a full and prolonged course of quinine followed by tonic treatment with arsenic and iron, Secure in their protected house from the baleful mosquito, this family has made an excellent recovery, although their convalescence and cure had to go on through the height of the malarial season Only one of the children, in whom the relapses were more obstinate, still remains in somewhat poor condition On this Castelgiubileo line the proof of the value of the new prophylaxis has thus been most decisive and eloquent *Of a whole community of persons all subjected to the same conditions in other respects, those whom we defended against mosquitoes have remained free from fever, whilst those left unprotected have nearly all been attacked* It is as if we had a book with its pages alternately white and black, the white pages corresponding to our protected houses and families, the black representing those left unprotected No less decisive in their results were the experiments made on the other lines

3 Pontegalera line Here, in the section outside of the protected zone, in cottages Nos 15 to 19 inclusive, out of 42 railway servants only three escaped the fever In our protected zone, on the other hand, out of 36 persons only two contracted it, while in the section further on, from the twenty seventh to the thirty third kilometre, out of 10 persons only one remained unattacked As further controls we had the station of Pontegalera, placed almost in the midst of our zone of experiment, where out of seven persons six were attacked, the first lineman's cottage on the Fiumicino railway, where all of the three inmates suffered, and some neighbouring country cottages in which at Chiesola 30 inmates out of 30 were attacked, at the hamlet of Pontegalera four out of four, and at a house placed almost midway between two of the protected railway cottages 12 persons out of 12

4 The Anzio line Here we selected for protection the two cottages most noted for malaria—namely, those at the twenty-fifth and thirty second kilometre Now in these two cottages, in each of which were four persons, all remained perfectly well, and four other persons who came from the Terracina line to live in them suffering severely from malaria recovered their health completely On the other hand, in the cottages from the eighteenth to the twenty-third kilometre, out of 39 inmates 36 sickened with fever, in the cottages lying between the two protected ones nine out of nine, and in those beyond our No 32 cottage eight out of 10 Among a squad of linemen numbering six there were four fever patients, the two who escaped belonging to the family protected by me at the twenty-fifth kilometre

5 The Terracina line In the railway cottages along this line, so terribly malarious, I had 30 persons protected between the station of Frasso and Terracina Of these only two suffered from primary infections—namely, a lineman who by mistake went on night duty without his mosquito hood and a little girl who had had quartan fever In two persons who had become malarial cachectics during the previous two years æstivo autumnal attacks recurred with obstinacy up to the first few days of October, in spite of treatment None of the others had malaria On this line also I was able to establish a series of controls analogous to those I have described on the Castelgiubileo line by leaving here and there cottages unprotected Of 37 persons inhabiting these latter 35 took fever

To sum up, of 207 railway employés subjected to the new prophylaxis against malaria during the seasons 1899 and 1900 only 10 contracted fever, although they were living in the most unhealthy regions of Latium and in the midst of their fellows, all or nearly all, of whom were stricken by the disease Also, in houses defended against the invasion of mosquitoes malaria loses its contagiousness and no longer gives rise to the usual epidemic Further, the treatment of, and convalescence from, malarial fever can be carried on in malarious localities in houses protected from the invasion of mosquitoes quite as well as in places where the air is good

It is to be noted, in conclusion, that this favourable result was obtained with the utmost simplicity, all that was necessary being a little persuasion with a small present, and the supervision which I and two railway officials who assisted me, one on the Adriatic and the other on the Mediterranean railways were able to exercise A similar result could therefore be attained wherever and whenever desired, and I am able to say that these two railway companies propose to secure it on the largest possible scale

B —PROTECTION OF THE CARETAKERS IN THE CAMPAGNA

Two Roman companies—namely, the Società dell' Acqua Marcia and the Società dell Elettricità—have each a caretaker's house on the road from Rome to Tivoli, both situated in localities with a bad type of malaria which has hitherto attacked the families residing in them every year, or rather, I should say, the wives and the five children, for the husbands, owing to many years of past suffering from the disease, have become immune This year for the first time the wives and children have escaped infection, and this immunity they owe to my having had their houses protected before the commencement of the malaria season in the same way as those of the railway people with wire netting As I had here to deal with persons of intelligence who could be trusted to carry out my instructions carefully I left this experiment to proceed, as it were, of its own accord At the beginning of the season I went with the companies' engineers, first to order, and then to approve, the protective arrangements for the houses I gave the requisite instructions (to remain indoors from an hour before sunset till an hour after sunrise and to kill any mosquitoes that might accidentally gain entrance) and after that I did not return From the engineers however, I have from time to time received news of the welfare of these people, together with thanks for the danger escaped The same protection may thus be secured whenever they desire by all the caretakers of the communal, provincial, and Government roads, of monuments, and of the works for reclaiming waste lands in the many malarious districts of Italy

C —PROTECTION OF THE PEASANTS

Malaria rages most of all among the field labourers, working as these do in the most dangerous hours of the evening and night at the most unhealthy time of year—namely, when the principal crops are reaped—living in habitations of a wretched or defective kind—or without any habitation whatever—and withal very insufficiently clad Such conditions render it very difficult to carry out among these people the prophylactic measures which would be, and ought yet to become of the greatest benefit to them socially I wanted notwithstanding this to make the attempt Accordingly, I protected in the usual way, with nets over the windows and doors, the hamlet on the farm of ' Le Castella ' and about half of the hamlet of the 'Cervelletta" Among the houses so protected on the latter farm was one with a terrible reputation for the number of victims which malaria had yearly claimed from it, so much so that the proprietor wished to shut it up Below this house, in which two families (six persons) were going to live, was another, a sort of tavern, which I also protected with the netting And, finally, I determined to make the same experiment with that most primitive of all human habitations, the straw hut closing thoroughly with straw all the holes in its sides, and with wire gauze the openings for allowing the smoke to escape, I placed at its entrance a big cage of the same material, furnished in its turn with two doors made to close automatically. I protected three huts in this way, two at the Cervelletta and one at the Castella.

It is more difficult to induce half-educated people to believe that malaria may be conveyed by the bites of mosquitoes than it is to convince the ignorant peasantry of the fact. On this account I met with much less difficulty from some of the more intelligent among the latter than I had expected in getting them to carry out the new prophylaxis so as to insure success.

In the hamlet of the Castella the family of the manager and the medical man of the Red Cross Society escaped infection, notwithstanding that some stagnant water from a ditch, which was brought into the house in an old cask, might have developed many mosquitoes. So also the 17 Lombard peasants who slept in the protected part of the hamlet of Cervelletta were rewarded for the great care they took by only one of their number falling sick with malaria, a man who was in the habit of getting drunk from time to time and while in this helpless state of sleeping in the open air. In the part of this hamlet which served as control we had at the same time 10 cases of primary infection and several relapses from the previous year's epidemic. And the house so cursed with the disease in former years had no fresh cases in it. One family was, however, obliged to leave its protection in the early days of September, and now (between Oct. 15th and 17th) the two children have already contracted fever.

In the midst of the other straw huts all stricken with malaria, the protected hut at the Castella, with a family, consisting of father (a very industrious man), mother, and three children, remained, wonderful to relate, quite free from fever, as did also one of the protected huts at the Cervelletta with five inmates—father and mother and three children. In this latter hut we never found mosquitoes; a few which found their way as far as the outside cage were killed. On the other hand, in the third protected hut, notwithstanding all our warnings, we found mosquitoes in the cage every morning and also often inside the hut itself. Finding it impossible to induce this family, on account of their apathy or their ignorance, to take the necessary precautions, we removed the protection, and three out of four of the inhabitants took fever. Thus, so long as the peasants were careful, they were able to defend themselves from malaria even in the most primitive of dwellings, the straw hut.

In order to protect from fever the nomadic rural population who come down to the Campagna at the season when the most dangerous kind of work is in progress, and who are easily infected on account of their sleeping in the open, the Caetani family are making a preliminary trial in the Pontine Marshes of a large hut constructed of wood and wire-gauze which can be taken to pieces and transported to wherever it is wanted.

Naturally, in order to make quite complete what we may call this mechanical prophylaxis for the peasantry it would be necessary to stop their work in the more dangerous hours. Besides this one must not lose sight of the ideal kind of prophylaxis for people who work—namely, that of making them artificially immune against the disease. With this object in view I have made, and continue to make many experiments, especially with euchinin, and I propose shortly to give an account of the results obtained by this medicinal method of procuring immunity. For the present I wish to insist upon the fact that by means of the mechanical prophylaxis for malaria (protecting the houses and the uncovered parts of the body) a great step in advance has been made for practical purposes. Among railway employés, caretakers, and even the peasants of the malarious Campagna the lesson of the last two years has been so persuasive that all of those who have hitherto served as controls are anxious to be protected during the next fever season. Within no very distant date all houses in malarious localities will be defended against the entrance of insects; thus during the day there will be no inconvenience from flies and other insects of an unclean, troublesome, or injurious kind, and at night there will not be the annoyance and evil effects of mosquitoes. In all low-lying, warm, moist places, where myriads of insects of every species swarm, this mechanical means of defence against their invasions will become the best of the prophylactic rules for the prevention of malaria and other diseases.

THE METROPOLITAN BOROUGH COUNCILS.

THE following list, compiled from official information, is a substantially complete enumeration of the medical men who have been elected members of the first metropolitan borough councils. There are, however, we believe, one or two vacancies to fill in consequence of the election of aldermen from the council, but the filling of these vacancies will probably leave the list unaltered.

Battersea.—Councillor: Mr. L. S. McManus, M.D., M.Ch. R.U.I.

Bermondsey.—Councillor: Mr. J. Mulqueen, L.R.C.P., L.R.C.S. Irel.

Bethnal Green.—Councillors: Mr. W. A. Farebrother, L.S.A., and Mr. F. E. Rogers, M.R.C.S. Eng., L.R.C.P. Lond.

Camberwell.—Councillor: Mr. A. Smith, L.R.C.P. Irel.

Chelsea.—Councillor: Mr. J. W. Erskine, B.A., M.B. T.C.D., L.R.C.S. Irel.

Deptford.—Councillor: Mr. F. T. Tayler, B.A., M.B., L.R.C.P. Lond., M.R.C.S. Eng.

Finsbury.—Councillor: Mr. E. Jones, M.R.C.S. Eng., L.R.C.P. Lond. (Chairman of the Public Health Committee).

Fulham.—Councillor: Mr. E. Cooney, L.R.C.P. Edin., L.F.P.S. Glasg., L.S.A., D.P.H. Camb.

Greenwich. — Mayor: Surgeon-Lieutenant-Colonel R. Gooding, V.D., M.D. Lond., M.R.C.S. Eng., J.P.

Hackney.—Aldermen: Mr. F. H. Daly, M.D. R.U.I., L.R.C.S. Edin., J.P., and Mr. T. Hoskin, L.R.C.P. Lond., M.R.C.S. Eng., J.P. Councillors: Mr. J. O. Adams, M.D. Durh., F.R.C.S. Eng., Mr. F. M. Miller, M.R.C.S. Eng., L.R.C.P. Lond., Mr. F. Wallace, L.R.C.P. Lond., M.R.C.S. Eng., and Mr. M. E. A. Wallis, L.R.C.P. Lond., M.R.C.S. Eng.

Hammersmith.—Councillors: Mr. C. C. Coker, L.R.C.P. Lond., L.S.A., and Mr. W. A. Davidson, L.S.A.

Hampstead.—Councillors: Mr. E. C. Andrews, M.D. Lond., M.R.C.S. Eng., Mr. C. W. Cunnington, M.R.C.S. Eng., Mr. A. O. Grosvenor, M.D. Edin., M.R.C.S. Eng., and Mr. F. E. Scrase, F.R.C.S. Eng.

Holborn.—Councillor: Mr. W. R. Smith, M.D. Aberd., F.R.S. Edin.

Islington.—Councillor: Mr. John Walker Smyth, L.R.C.P., L.R.C.S. Edin.

Kensington.—Councillor: Mr. F. H. Alderson, M.B. Durh., M.R.C.S. Eng., L.R.C.P. Lond., and Mr. E. D. Vinrace, M.R.C.S. Eng.

Lewisham.—Alderman: Mr. J. W. Elliott, M.R.C.S. Eng., (retired). Councillors: Mr. F. J. L. Hart, M.B., C.M. Edin., Mr. F. S. Smyth, F.R.C.S., L.R.C.P. Edin., and Mr. H. Visger, M.R.C.S. Eng., L.S.A.

St. Marylebone.—Councillors: Mr. L. A. Bidwell, F.R.C.S. Eng., and Mr. J. Edmunds, M.D. St. And., M.R.C.P. Lond., M.R.C.S. Eng.

Paddington.—Councillors: Mr. J. L. Atkinson, L.S.A., Mr. B. F. Popham, M.D. St. And., L.R.C.S. Irel., L.S.A., Mr. A. Prince, L.R.C.P. Edin., M.R.C.S. Eng., and Mr. D. A. Waite, M.A. Oxon., M.R.C.S. Eng., L.R.C.P. Edin.

St. Pancras.—Alderman: Mr. W. Smith, M.R.C.P. Edin. Councillors: Mr. J. A. Angus, Mr. W. F. Hazel, M.R.C.S. Eng., L.S.A., Mr. R. P. Long, L.F.P.S. Glasg., L.S.A., Mr. E. F. T. MacCarthy, L.R.C.P., L.R.C.S. Irel., Mr. R. Paramore, M.D. Brux., M.R.C.S. Eng., and Mr. J. Thompson, M.D. St. And., M.R.C.S. Eng., L.R.C.P. Edin.

Shoreditch.—Councillor: Mr. J. Davies, M.D. Durh., M.R.C.S. Eng., L.S.A.

Southwark.—Alderman: Mr. W. G. Bott, L.R.C.P. Edin., M.R.C.S. Eng. Councillor: Mr. E. C. Perry, M.A., M.D. Cantab., F.R.C.P. Lond., M.R.C.S. Eng.

Stoke Newington.—Councillor: Mr. R. Ostlere, M.B., C.M. Aberd.

Wandsworth.—Alderman: Mr. T. A. Ives Howell, L.R.C.P. Lond., M.R.C.S. Eng. Councillors: Mr. J. Gay, L.R.C.P. Lond., M.R.C.S. Eng., Mr. C. R. Lucas, M.R.C.S. Eng., L.R.C.P. Lond., and Mr. Mark Robinson, M.R.C.S. Eng., L.R.C.P. Lond.

Westminster.—Councillor: Mr. H. A. Des Vœux, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng.

Woolwich.—Councillor: Mr. J. Jeken, M.R.C.S. Eng., L.S.A.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

On the Sanitary Condition of the Borough of Windsor, and upon the Character of the Town Council's Administration, by Dr H TIMBRELL BULSTRODE [1]—Attention is drawn elsewhere in our present number to the immediate circumstances which determined the issue of this report It would seem, however, that the sanitary condition of Windsor has on several previous occasions been the subject of investigation for the Local Government Board, particularly in 1886 when, in consequence of local demands following on the publication of the report [2] an inquiry was held by Dr H Airy and Mr Arnold Taylor, and a series of official recommendations to the Town Council was issued

In the present report ample evidence appears that the backwardness of local administration in Windsor, which was conspicuous 15 years ago, has largely remained a characteristic of the borough If this has been due mainly to the ignorance or apathy of the Windsor public Dr Bulstrode has now done much to enlighten them Departing from the somewhat frigid recital of facts of which official reports are apt to consist, he has produced a document which should certainly succeed in capturing the attention of that important person in modern politics, the "man in the street" After giving details as to the present estimated population (12 716) and a description of the physical and geological features of the town, Dr. Bulstrode deals with its water supply Shallow wells, which used to be common in Windsor, have now disappeared, and the public supply of the Windsor and Eton Waterworks Company serves the whole district This supply is obtained by pumping from several wells sunk in river gravel alongside the Thames the source of supply being largely composed of subsoil water and of Thames water which has percolated to the wells through a greater or less thickness of natural gravelly soil The water is not filtered before being pumped into the service pipes Certain of these wells are within a few yards of inhabited dwellings but Dr. Bulstrode was assured that special precautions had been taken as regards the sewers serving these houses Although, having regard to the sources of supply, systematic examination, chemical or bacterial, of water from each separate well is unquestionably desirable, the only examination hitherto practised has been occasional chemical analyses made for the water company of samples taken from the town mains, which of course represent a mixture of water from all the wells

As regards excrement disposal, "up to a comparatively recent date there was a large number of closets not provided with water, and the unsatisfactory method of hand flushing was resorted to" Much amendment in this respect has however, been lately made With respect to house drains in the poorer parts of Windsor their "nature, direction, and soundness is usually a matter of pure conjecture Ventilation is often entirely absent, as also are opportunities of drain inspection Probably but few of the older drains would withstand the water test, and it does not seem that any very extensive effort has been made to ascertain the exact state of affairs in this respect Numerous instances of defective and broken traps came to my notice and on several occasions complaints of smells from the house sinks were made" These drains were probably laid before the existing by laws came into force; in certain new houses, however, Dr Bulstrode found that in laying house drains the by laws had been contravened

The sewers of Windsor are of diverse kinds "Some are old brick barrel sewers, others pipe sewers with clay joints, and others again, as for instance the more recent, pipe-sewers with proper joints The levels vary considerably, and in certain instances the fall of the sewer is in the opposite direction to the flow of sewage" The contents of the main outfall sewers are pumped on to a sewage farm on an island at Old Windsor This outfall sewer is liable to be blocked during a considerable portion of each 24 hours when pumping is not going on, and hence "acts as a storage tank', this accumulation "must place great strain on the sewers and facilitate deposit in them, a fact easily verified by an examination of the walls of the inspection chambers" Surface water and drainage, which reaches Windsor sewers by the "Clewer ditch," give rise to considerable inconvenience by increasing the pumping requirements House refuse in the poorer parts of Windsor is often stored in ash-pits which are much dilapidated or altogether broken down, and frequently heaps of refuse are allowed to accumulate on the bare ground ' In times of rain this decomposing refuse is washed into the subsoil in the neighbourhood of inhabited houses, and in times of drought and wind is scattered broadcast This aspect of public health control in the borough has there can be no doubt been much neglected" Save for a temporary structure for cases of small-pox, situated alongside the sewage farm, there is no isolation hospital for the borough Dr Bulstrode points out that some responsibility in this matter attaches to the medical officer of health, Dr E Casey, whose advice to the town council shows that his views on the subject "are not those held by the vast majority of his colleagues in the public health service" These views Dr Bulstrode combats, setting out in reply a temperate claim for the utility of isolation hospitals on broad lines of expediency to the community and advantage to the individual

With regard to the housing of the poor of Windsor Dr. Bulstrode shows that a most undesirable state of affairs exists. He gives in illustration detailed notes of his inspection of Victoria Cottages, a row of about 100 houses with dilapidated roofs, falling ceilings, unpaved yards, defective gullies broken rain-pipes, accumulations of refuse in backyards, and many other deficiencies rendering them, in his view, "difficult to regard as suitable for human habitation" Of this visit he says: "I was especially invited to enter certain houses, the tenants beckoning to us to inspect their abodes and to see the conditions under which they were obliged to live There was distinctly a pathetic side to this inspection of Victoria Cottages, the inmates seeing members of the town council with me, thinking that at last at any rate, there would be some redress" In other streets, such as River-street (formerly Bier lane, which figured prominently in the report in THE LANCET in 1885), Distil House row, Red Lion-row court, Garden court, Keppel row, and Queen's square, numerous instances of hopelessly dilapidated and overcrowded dwellings are also detailed In the common lodging houses the custodians were frankly ignorant of, and systematically transgressed, the borough by-laws—a copy of which the inspector seems to have had considerable difficulty in securing. Slaughter house by laws were also disregarded As regards storage of milk in many cases "the circumstances under which the cleansing and the storing of the milk pans were carried out left much to be desired, and customers would not have been reassured by a visit to these places"

Dr Bulstrode reviews in considerable detail the attitude of the town council (which he describes as "without backbone") and their officers towards the measures of sanitary progress which should have been taken to remedy the various evils which he has described Taking as instances certain specific nuisances he gives a chronological history of the dealings of the local authorities with them From these we gather that five years of reports and discussion may not suffice to produce amelioration in some of the worst dilapidated cottage property in the place, and that it may take the sanitary inspector four years of reports and orders before a proper supply of water can be obtained for a closet

Not the least instructive part of the report lies in the indications furnished by the inspector of the degree of responsibility respectively attaching to the town council and to their officers in matters such as these That his inspection resulted in immediate improvement in certain directions is evidenced by a memorandum by the town council which is appended to the report This circumstance seems hopeful for the future

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6323 births and 3923 deaths were registered during the week ending Nov 24th The annual rate of mortality in these towns, which had been 17·6, 16 9, and 17·6 per 1000 in the three preceding weeks, was again 17·6 last week. In London the death-rate was equal to 17·2 per 1000, while it averaged 17.9 in the 32 provincial towns. The lowest death-rates in these towns were 10 0 in Norwich, 10 5 in Cardiff, 11 5 in Huddersfield, and 13·1 in Croydon; the highest rates were 21·0 in Manchester and in Preston, 21·9 in Liverpool, 23·2 in Bolton, and 24·3 in Salford. The 3923 deaths in these towns included 351 which were referred to the principal zymotic diseases, against numbers decreasing from 485 to 353 in the four preceding weeks; of these, 76 resulted from diphtheria, 68 from whooping-cough, 65 from "fever" (principally enteric), 58 from measles, 46 from diarrhœa, and 38 from scarlet fever. No death from any of these diseases occurred last week in Wolverhampton; in the other towns they caused the lowest death-rates in Bristol, Cardiff, Norwich, and Newcastle, and the highest rates in Brighton, Swansea, Blackburn, and Sheffield. The greatest mortality from measles occurred in Swansea and Gateshead; from whooping-cough in Derby, Preston, and Sheffield; from "fever" in Plymouth; and from diarrhœa in Swansea, Blackburn, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the 33 towns. The 76 deaths from diphtheria included 22 in London, 12 in Sheffield, eight in Leicester, six in Leeds, and five in Liverpool. No fatal case of small-pox was registered last week either in London or in any of the 32 large provincial towns; two cases of small-pox were admitted into the Metropolitan Asylums hospitals during last week, and both remained under treatment on Saturday last, Nov. 24th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2725, against numbers increasing from 1703 to 2728 on the 12 preceding Saturdays; 246 new cases were admitted during the week, against 336, 289, and 261 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 164 to 352 in the seven preceding weeks, declined again last week to 321, and were 106 below the corrected average. The causes of 51, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, and Newcastle, and 11 other smaller towns. The largest proportions of uncertified deaths were registered in Liverpool, Huddersfield, Sheffield, and Gateshead.

[2] Report of THE LANCET Special Commission on the Sanitary Condition of Windsor; THE LANCET, August 15th, 1885 p 306

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2 and 19·9 per 1000 in the two preceding weeks, further rose to 20·3 during the week ending Nov. 24th, and showed an excess of 2·7 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·9 in Leith and 16·9 in Edinburgh, to 24 9 in Greenock and 25·2 in Paisley. The 628 deaths in these towns included 25 which were referred to whooping-cough, 20 to diarrhœa, 8 to measles, six to "fever," five to scarlet fever, 4 to diphtheria, and one to small-pox. In all, 69 deaths resulted from these principal zymotic diseases, against 62 and 75 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·2 per 1000, which was 0·6 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 22 in each of the two preceding weeks, increased last week to 25, of which 17 occurred in Glasgow and five in Greenock. The deaths from diarrhœa, which had declined from 53 to 16 in the seven preceding weeks, rose again to 20 last week, and included seven in Glasgow, four in Dundee, three in Edinburgh, and three in Aberdeen. The fatal cases of measles, which had been five and 13 in the two preceding weeks, declined again last week to 8, of which five were registered in Aberdeen and two in Edinburgh. The deaths referred to different forms of "fever," which had been seven in each of the two preceding weeks, declined to six last week, and included three in Glasgow and two in Aberdeen. The fatal cases of scarlet fever, which had been four in each of the two preceding weeks, rose last week to five, and were all registered in Glasgow. The deaths from diphtheria, which had been seven and 11 in the two preceding weeks, declined last week to four, of which two occurred in Glasgow, where the fatal case of small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 98 to 163 in the seven preceding weeks, declined again last week to 156, and were 28 above the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 20·0 to 26·0 per 1000 in the four preceding weeks, further rose to 26·1 during the week ending Nov. 24th. During the past four weeks the death-rate in the city has averaged 24·1 per 1000, the rate during the same period being 17 0 in London and 17·4 in Edinburgh. The 175 deaths belonging to Dublin registered during the week under notice were one in excess of the number in the preceding week, and included 19 which were referred to the principal zymotic diseases, against 11 in each of the two preceding weeks; of these, eight resulted from "fever," five from whooping-cough, five from diarrhœa, and one from diphtheria. These 19 deaths were equal to an annual rate of 2·8 per 1000, the zymotic death-rate during the same period being 1·3 in London and 1·0 in Edinburgh. The deaths referred to different forms of "fever," which had been four and three in the two preceding weeks, rose again last week to eight. The fatal cases of whooping-cough, which had been one and two in the two preceding weeks, further increased to five last week. The deaths from diarrhœa, which which had been six and three in the two preceding weeks, rose again last week to five. The 175 deaths in Dublin last week included 30 of infants under one year of age and 38 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a marked decline. Five inquest cases and three deaths from violence were registered, and 63, or more than a third, of the deaths occurred in public institutions. The causes of 13, or more than 7 per cent., of the deaths in the city last week were not certified.

ROYAL LONDON OPHTHALMIC HOSPITAL GUILD.

THE first annual meeting of the Royal London Ophthalmic Hospital Guild was held in the board-room of the hospital on Thursday, Nov. 22nd. Mrs. JOHN TWEEDY, the chairman of the committee, who presided, in briefly summarising the aim and scope of the work of the Guild, said that its primary object was to aid the hospital by supplying special clothing for the use of the patients. The work of the past few months had been so satisfactory that the committee thought themselves justified in attempting to place the Guild upon a larger and more important basis, and with this object in view the patronage and coöperation of ladies well known for their interest and energy in good works was sought. The Lady Mayoress had consented to become the first President of the Guild The great aim of the Guild would be the creation of a sinking fund for the hospital. It was sad to find a hospital, the pioneer and teacher in eye diseases, struggling for life through lack of funds. If the Royal Ophthalmic Hospital could feel sure of a sinking fund of £80 000 the interest would defray the expenses of rent, rates, and lighting.

The report, a very satisfactory one, was then proposed and adopted.

Lady Russell Reynolds, Lady Avebury, and Mrs. John Tweedy were subsequently appointed vice-presidents, Mrs. Gunn was re-appointed honorary treasurer, and Miss Braybrook secretary.

Among the rules of the Guild are the following:—

> The objects of the Royal London Ophthalmic Hospital Guild are. (*a*) To provide some ward clothing for the patients while in the hospital, and to aid the hospital by giving garments for the operating theatre and the necessary household linen. (*b*) To promote any other work in connexion with the hospital which may from time to time commend itself to the council of the Guild.
>
> The Guild consists of members (men and women) who are (*a*) Patrons, invited by the Council; (*b*) Working Members elected by the Executive Committee, contributing not less than 2s. 6d. annually, and also undertaking to furnish two garments per annum for hospital use, or to pay an additional sum of 2s. 6d. in respect of each garment; and (*c*) Associates, contributing not less than 5s. annually.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons F. J. Lilly to the *Doris* and G. S. Smith to the *Blake* and subsequently to the *Empress of India*; Surgeons M. C. Langford to the *Defiance* and R R Fasson to the *Blake* and subsequently to the *Empress of India*.

ROYAL ARMY MEDICAL CORPS.

Colonel Napoleon B. Major is placed on temporary half-pay on account of ill-health. Major Charles James Addison retires from the service receiving a gratuity.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the retirement from the service of the under-mentioned officers:—Lieutenant-Colonel Richard Careless Sanders, Bengal Establishment; Lieutenant Colonel Henry David Cook, Madras Establishment; and Lieutenant Ernest Le Fevre Payne, Madras Establishment, half-pay.

VOLUNTEER CORPS.

Artillery: 1st Lincolnshire (Western Division, Royal Garrison Artillery): Surgeon-Captain T. W. J. Allen resigns his commission. *Rifle:* 14th Middlesex (Inns of Court): Arthur Maitland Ware to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

Civil Surgeon Stewart Kirkpatrick, R A.M C., who is ordered for duty in South Africa, sailed from Southampton in medical charge of the troops on board the *Tagus* on Nov. 27th

Lieutenant L. N. Lloyd, R.A.M.C., Civil Surgeon A. E. Robinson, Civil Surgeon E A Hauseman, Major C. E. Faunce, R.A.M.C., Captain F. J. Wade-Brown, R.A.M.C., Civil Surgeon H. Baylis, I.M.S., Civil Surgeon N B. Harman, and Civil Surgeon H. B. Maunsell have been discharged from hospital to duty.

Colonel A. W. Duke, R.A.M.C., and Major J. W. Jérome, R.A.M.C., are returning home invalided in the *Goth*.

Major W. G. A. Bedford, R A.M.C., Major J. G. Black, R.A.M.C, and Captain K. M. Cameron, R.A.M.C., are returning home invalided in the *Simla*.

ARRIVAL OF SURGEON-GENERAL W. F. STEVENSON AT NETLEY ON HIS RETURN FROM THE SEAT OF WAR.

There were great rejoicings at Netley on Nov. 24th, on the occasion of the return of Surgeon-General W. F. Stevenson from the seat of war in South Africa. Some days before his arrival the ladies of the station had formed themselves into a reception committee with a view to the decoration of the railway station and the route thence to Surgeon General Stevenson's residence. Under the guidance of the committee and with the help of the non-commissioned officers and men of the Royal Army Medical Corps, and of the coastguards and railway employés, the railway station and roadway were most tastefully and appropriately decorated. The whole of the station was hung with Union Jacks and other flags and the entrance room was adorned with banners and flowering plants, flags, and devices. Three frames were erected on which were words and mottoes picked out in green leaves on a white ground. On the arrival platform the words were "Welcome Home"; on the departure platform (Southampton) was the motto of the Royal Army Medical Corps, "In arduis fidelis"; while over the gateway leading to the Surgeon-General's house was a triumphal arch bearing the Celtic motto, "Cead mille failthe." The *Tantallon Castle*, in which Surgeon-General Stevenson travelled home, was sighted off Hurst Castle at five minutes past 12 o'clock and she arrived at the Southampton Docks soon after 2 P.M. Surgeon-General Stevenson was the first officer to land and was met by his wife and daughter and some friends. Leaving Southampton shortly before four o'clock the party travelled to Netley, and arriving there at 4.25 P.M. they were received by the whole of the staff of the Royal Victoria Hospital and of the Army Medical School, in which latter institution the welcomed officer had so long served as Professor of Military Surgery, and by a large body of the general public resident in and around Netley. Surgeon-General Stevenson was most warmly cheered, both on his stepping on to the platform from the train and on his entering the carriage to drive to his home. All the houses on the route were gay with decorations, poles and bunting having been erected and streamers placed across the roadway over head. It will be remembered that Surgeon-General (then Colonel) Stevenson left Netley on Oct 22nd, 1899, in the *Gascon* for South Africa, where, on arrival, he took over his appointment as principal medical officer of the line of communications in Cape Colony and in the Boer States and as consulting surgeon to the forces. From the time of the arrival of Lord Roberts at the front Colonel Stevenson, who was promoted by the Commander-in-Chief to be a local surgeon-general, formed one of the head-quarters staff and accompanied Lord Roberts throughout the campaign. Surgeon General Stevenson was only one day unfit for duty during the 13 months of his arduous work. The reception accorded to him at Netley on his return was a proof of the esteem and affectionate regard in which he is held by his brother-officers and by that section of the general public to which he is so well known.

THE POST OF COMMANDER-IN-CHIEF.

Sir Evelyn Wood is, in a way, filling the post of an Acting Commander-in-Chief pending the arrival of Lord Roberts, who is expected to be in England towards the end of the year. Notwithstanding that Lord Wolseley had consented at the request of the Government to remain in office as Commander-in-Chief until the end of November his retirement before the arrival of Lord Roberts in this country to take up the appointment has naturally given rise to some surprise. People are curious to know whether there is any truth in the rumoured existence of somewhat strained relations between the Horse Guards and the War Office. Although the matter is, of course, one of national interest it has nevertheless a bearing upon the medical as well as upon every other branch of the military service. Army medical organisation and the Royal Army Medical Corps will come in, too, for a good deal of consideration both inside and outside the War Office. It will be remembered that Lord George Hamilton, when speaking lately at Ealing, referred very pointedly to Lord Lansdowne, and stated that the late Minister for War had carried with him to his new office the goodwill and admiration of every one of the colleagues with whom he had been working for the past five years. "A good many of Lord Lansdowne's detractors would be shamefaced when the source of the disasters was made known. No man ever maintained a more chivalrous and magnanimous attitude than did Lord Lansdowne during the dark and dreary days of the war last year." It is easy to understand that the lines of demarcation between the functions of the civil and military branches of the War Department are not always very definitely defined but may occasionally overlap. The meeting of Parliament will be of great interest and fraught with important issues; meanwhile Mr. Brodrick is understood to be working away at his hard task of army reforms. In taking official and regretful leave of Lord Wolseley the nation does not forget the services which he has rendered. If he has never commanded a force against a European foe he has, nevertheless, been successful in the expeditions he has undertaken, has had a long and brilliant war service, and is a thorough soldier. He has, moreover, been largely instrumental in introducing some radical, far-reaching, and good changes in the army.

THE ROYAL NAVY LIST DIARY AND NAVAL HANDBOOK.

This is the fourth yearly issue of a diary and handbook which is of great use, both to naval men and others who are in any way interested in our first line of defence. The excellent diary gives a page to each day with complete schedules for recording drills and the making up of returns, while the miscellaneous information usually found in diaries is such that every officer in the Royal Navy must appreciate its value. Among this information is the following:—A Summary of the Year's Naval Progress by L. Carr Laughton; *The Navy Estimates* for 1900–1901, with full Statistical and Comparative Tables, the Naval Obituary for the Year, with the War and Meritorious Services of Deceased Officers; Tables of Tides and Tidal Constants and Monthly Astronomical Ephemeris; Original Descriptive Articles on the Tides and Terrestrial Magnetism; the Night Signals of the Principal Lines and Signals of Distress (revised to date); and List of Benevolent Funds and Institutions in connexion with the Navy. Messrs. Witherby and Co., 326, High Holborn, are the publishers, and the price is 3*s.* net.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The staff and members of the school entertained Major R. R. Sleman and Captain E. W. St. Vincent Ryan, two of the medical officers of the C.I.V., at dinner at the Florence Restaurant on Friday evening, Nov. 23rd. A large number assembled under the presidency of Brigade-Surgeon-Lieutenant-Colonel P. B Giles, V.D., senior medical officer. Two toasts only were given—"The Queen" and "Our Guests." In responding for the guests Major Sleman bore testimony to the gallantry of the C.I.V. stretcher-bearers in all the engagements in which the corps took part. At the action fought near Frederickstad on July 31st, Private C. J. Day and Private W. Shrimpton rushed forward to help a wounded yeoman in answer to an urgent message, and were both killed. Private T. Cooper at once volunteered to take their place. At the battles of Zand River and Diamond Hill the C.I.V. bearers did good work with both British and Boer wounded, and in the hospitals at Orange River and Glen they materially helped the Royal Army Medical Corps in coping with severe epidemics of enteric fever. Captain Ryan gave his experiences with the mounted infantry, and spoke of the chase after Cronje and his capture, describing also his visit to the laager to treat the Boer sick and wounded. The arrangements for the banquet were carried out by Surgeon-Captain Callender and a very enjoyable evening was spent.

ENDURANCE.

The following passage is extracted from a letter of Mr. Wilfrid Appleyard, a lieutenant in the 2nd East Surrey Regiment, now in garrison at Platrand, to his father, Mr. J. Appleyard of Park Grange, Sheffield:—

> Platrand, Transvaal, Oct. 31st, 1900
>
> ..... Yesterday we had another instance of Boer brutality and a wonderful proof of the remarkable endurance and vitality of savage races. It is not very nice family reading, but I must tell it you, as it seems to me to be such a really marvellous instance of endurance. Yesterday morning a Kaffir was admitted into our lines with his head lacerated most terribly. He actually walked into camp with a hole right through his head and his brain protruding through the wound and dried on to his forehead by the sun. He was a fearful sight, and his head was literally covered with flies. We handed him over to the doctor, to whom he afterwards stated that he had walked all the way from a Boer laager about 20 miles away. He had had a quarrel with his master, a Boer on commando, who as a punishment had broken his thumb with a sjambok and afterwards placed a revolver to the back of his head and fired a bullet through it. The native was left in a donga for dead, but after lying senseless for three days, exposed to the sun and flies by day and the cold by night, he actually walked the whole distance without food until he reached our camp. Our doctor takes it as an affront to medical knowledge that the man should be alive and has sent him to the hospital at Standerton for examination by the medical staff there.

DEATHS IN THE SERVICES.

Deputy Surgeon-General George Mackay died suddenly at his residence, 2, Learmonth-terrace, Edinburgh, on Nov. 20th, aged 88 years. In 1842 he received a commission in the Medical Department of the Honourable East India Company, and took part in the operations against the Mahrattas in 1844. In Burma in 1852 he was present at the actions which culminated in the capture of Rangoon and also at the occupation of Prome and Meaday (medal and clasp for Pegu), and was specially thanked for his services during the campaign. In 1864 he was appointed to the Military Finance Department of the Government of India. He retired in 1875.

Deputy-Surgeon-General James Carroll, on Nov. 27th, at his residence in Dublin.

THE WAR IN SOUTH AFRICA.

The daily journals have been bristling with interesting and exciting news of late in regard to the renewed activity in various directions of the scattered and disorganised Boer forces, the plot against Lord Roberts, the return of some of our troops to this country, and the presence of Mr. Kruger in France; but there is little or nothing of medical interest to be chronicled.

ROYAL LONDON OPHTHALMIC HOSPITAL. — A concert in aid of this hospital will be given at the Sandringham Club, 38 Dover-street, W., on Dec. 13th, at 3.30 P.M., arranged by Mrs. Bertram Blount. Tickets, 7*s.* 6*d.* each, or three for one guinea, can be obtained from the secretary of the club; from Mrs. Bertram Blount, 48, Bedford-gardens, W.; from Mrs. Dwelly, 18, Dawson-place, W.; or from Mrs. MacCallan, 32, Bedford-gardens, Kensington.

Correspondence.

"Audi alteram partem"

"OUR WIDOWS AND ORPHANS."

To the Editors of THE LANCET.

SIRS,—I was glad to see in THE LANCET of Nov. 17th (p. 1459) a letter from Mr. Christopher Heath pointing out the advantages of joining early in life the Society for the Relief of Widows and Orphans of Medical Men. Will you allow me, as one of the directors and therefore as being acquainted with the working of the society, to echo the president's appeal and to urge those of my younger brethren who are still at one of the London hospitals or who have recently commenced the practice of their profession somewhere within the prescribed radius of 20 miles from Charing-cross to become members? With this object I should like to mention but one out of many cases that might be quoted, and I will select the case to which Mr. Heath happened to allude in his letter. It occurred only the other day and will answer my purpose as well as any other. A medical practitioner who joined the society in 1891 died in March of the present year in Australia from the effects of an accident. His widow, who after paying all the debts found that the only provision for herself and her seven children was an insurance of £500, came home to this country not knowing what she was to do or which way to turn. The ages of the children ranged from 12 years to a few months. Knowing that her husband had subscribed to this society she made inquiries and was advised to lay her case before the directors. The facts of the case were investigated and to her surprise and joy she had allotted to her a grant for herself at the rate of £50 per annum and a grant at the rate of £10 per annum for each of the five eldest children, making a total of £100 per annum. In addition to this she will receive from the society a Christmas present of £25. The total amount her husband had paid in subscriptions was 19 guineas Could there be a more striking illustration of the benefits that may accrue from belonging to this society? The two-guinea subscription is an investment to which it would be difficult to find a rival. It ensures—and only think what a comfortable reflection this is for a beginner — substantial help for the widow and children in case of premature decease, and in the event of the subscriber being able to leave his family sufficiently well off not to need help from outside the money goes to the relief of others less fortunately situated, and the annual subscription becomes one of the most admirable and deserving forms of charity to which a medical man, as such, can be called upon to contribute—a charity in the benefits of which only the thrifty can participate.

The society is worked at an almost absurdly small expense (most of its officers, including its solicitor, being unpaid) and its invested capital amounted on May 1st, 1900, to £97,687. Its financial soundness is therefore beyond question. Last year its total receipts available for payments were £3353, and, as its expenses were considerably below £250, it was able to make grants during the year to the extent of over £3000 Anyone who is sufficiently interested to desire further information may obtain it from the secretary, Mr. J. B. Blackett, 11, Chandos-street, Cavendish-square, W., who will also be glad to furnish forms of application.

I am, Sirs, yours faithfully,
CHARLES J CULLINGWORTH.

Manchester-square, W., Nov. 26th, 1900.

EPIDEMIC PERIPHERAL NEURITIS

To the Editors of THE LANCET.

SIRS,—During the last six months I have been particularly struck with the large number of cases of alcoholic neuritis in this large Poor-law infirmary. Although there are generally a few cases in the wards (an average of 13) of late the number has been startling, and at the present time 52 cases of alcoholic peripheral neuritis are in this hospital. The large majority of the cases are amongst women and in many instances only a moderate amount of beer or porter has been taken. Careful investigation goes to show that in nearly all the cases the patients drank beer or porter and not spirits. The association of pigmentation in many cases occurring suddenly and rapidly, completely covering the whole body, the occurrence of eruptions and soreness of the eyes, pointed to the suggestion that there was some poisonous agent in the food or drink, and a new light has been thrown upon the matter by Dr. E. S. Reynolds of Manchester who has actually found arsenic in samples of beer. This short note is only intended as preliminary, and as the subject is of such great importance the cases will be published in full at some future period.

I am, Sirs, yours faithfully,

NATHAN RAW, M D. Durh., F.R.C.S. Edin,

Nov. 28th. Medical Superintendent, Mill-road Infirmary, Liverpool.

THE MEDICAL DEGREE OF THE UNIVERSITY OF BIRMINGHAM.

To the Editors of THE LANCET.

SIRS,—A paragraph in the letter of your Birmingham Correspondent in THE LANCET of Nov. 24th, p 1536, relating to degrees for practitioners, has led to a certain amount of misunderstanding. May I point out that the ordinance, of which I inclose a copy, only refers to those gentlemen who have taken out their entire course of medical study in the Birmingham School of Medicine?

I am, Sirs, yours faithfully,

BERTRAM C. A. WINDLE,

Dean of the Faculty of Medicine, University of Birmingham.

Nov. 26th, 1900.

[INCLOSURE.]

ORDINANCE CONCERNING PRIVILEGES OF PAST STUDENTS OF THE BIRMINGHAM MEDICAL SCHOOL.

That past students of the Birmingham Medical School who have taken out their whole course in Birmingham, and are duly qualified medical men, be permitted at any period during the five years commencing on the 1st of October, 1900, to present themselves for a Final Examination for the Degrees of Bachelor of Medicine and Surgery.

Subjects for examination—(*a*) *Medicine, including therapeutics; (*b*) *surgery and operative surgery; (*c*) *midwifery and gynæcology; (*d*) pathology and bacteriology, and (*e*) forensic medicine and toxicology.

* This examination will consist of three parts (1) written papers; (2) *viva voce*; and (3) clinical

Approved by the University Council, June 13th, 1900.

"THE VESTRY OF CAMBERWELL AND THE ANTITOXIN TREATMENT OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—As the writer of the report and circular alluded to by your correspondent "Camberwell" I could not but be aware of the possibility that a certain amount of opposition would be aroused by them. At the same time, as they received the sanction of a committee on which two medical men sat (one as chairman) I feel that the responsibility is taken off my shoulders. I may, however, ask to be allowed to state in reply to "Camberwell" that the statement that antitoxin would cure 99 per cent. of cases was limited, in express terms, to "first-day" cases, though the quotation of the whole sentence would hardly have given pith to his criticism. As regards both this statement and the one as to the duration of prophylactic effect, I may say that all the most reliable statistics confirm them both. The case-mortality appears to me abundantly to justify the supposition that the use of antitoxin is confined to a small number of practitioners, and this mortality is deliberately under-estimated in my report, so as to avoid exaggeration.

One other letter in terms similar to those of "Camberwell" has reached me, and the writer now sends me his cases. Other communications in a very different strain have also come to hand and other sanitary authorities have made inquiries as to our system with a view to its adoption in their own districts. The number of cases, moreover, sent in for examination has nearly doubled since the issue of the report and circular, so that on the whole I feel justified in believing that "Camberwell's" opinion is shared by few. That Camberwell's practice may be followed by many other boroughs is my earnest hope.

May I be allowed, in conclusion, to refer to one important point in all such arrangements? The value of the provisions is considerably lessened if they are not at all times available. This being a private laboratory, though used for municipal purposes, specimens are received and reported on practically at any time throughout the year. If arrangements for this cannot be made the service which the offer of free diagnosis is capable of rendering is greatly detracted from. A laboratory which is closed from, say, 1 P.M. on Saturday to 10 A.M. on Monday, and observes Bank and other holidays, will often not be available when its services are most needed.

I am, Sirs, yours faithfully,

EDWARD C. BOUSFIELD,

Bacteriologist for the Borough of Camberwell.

Old Kent road, S.E., Nov. 24th, 1900

MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—I agree absolutely with the opinion expressed by Dr. H. E Armstrong in his letter in the *Times* of Nov. 13th. But I do not think he quite touches upon the question how this preliminary teaching of chemistry and the like can be best obtained and subsequently utilised. The council and staff of Epsom College have long held that the subjects referred to by Dr. Armstrong should be taught thoroughly as school subjects; at the same time the future student should not be allowed to specialise in science subjects until his general education has reached a certain standard and his faculties have been trained so as to be able to gain a firm hold of the elementary principles. Every student should be sent to a school where science is taught and the teaching recognised by the medical examining bodies. After he has passed through the ordinary course of study necessary for a good education he is introduced to the lecture room, the chemical laboratory, and the biological-room, and in a class of, say, 20 students each individual works under the personal superintendence of his teacher and he is taught as far as possible to get an intelligent grasp of the subjects brought before him. In fact, our plan has been to teach all the subjects required for the matriculation and preliminary scientific examinations of the University of London, and the majority of our boys pass one or both of these tests. Many have also succeeded in obtaining scholarships afterwards at Oxford or Cambridge and winning honours in the university examinations. After leaving his school or the university the student joins a hospital fitted to spend the whole of his five years' curriculum in the pursuit of those advanced subjects comprised in a sound medical education. It is common experience that the subjects taught in the smaller forms possible in a public school are better remembered and more readily available for practical use than when the individual relation of teacher and taught is lost in the larger lecture theatres of the great medical schools.

Few teachers of experience will question the statement that the results of the teaching of scientific subjects are bound to be of little use and "practically *nil*" if those subjects are taught prematurely, before the mind has been fitted to grasp their first principles, by a course of training suited to early years, or if, again, a mass of crude facts is imparted where the intelligence has not been awakened or the ground properly prepared.

I am, Sirs, yours faithfully,

C. HOLMAN,

Treasurer of Epsom College.

Nov. 27th, 1900

"THE ALLEGED EXISTENCE OF A 'FOURTH DISEASE.'"

To the Editors of THE LANCET.

SIRS,—It is certainly surprising that the alleged discovery of a new zymotic disease by a medical man of repute—a disease, too, materially affecting the diagnosis of another disease so important, from a diagnostic point of view, as scarlet fever—has called forth so little comment from epidemiologists. If Dr Clement Dukes has indeed discovered a new malady of the nature he claims, the discovery is a highly important one and deserves due recognition. If, on the other hand, as I maintain, he has only been describing under the name of a new disease three series of cases the first two of which were in reality rose-rash, and the last one scarlet fever, then it is most desirable that this should be demonstrated Otherwise confusion will be worse confounded and numerous cases of indefinite but true scarlet fever are likely to be diagnosed as "fourth disease," to the detriment of the public and the discredit of our profession. This must be my excuse for again troubling you.

The main point upon which I join issue with Dr. Dukes is as to the identity of the various epidemics which he describes. If I am right in believing that he is describing more than one disease, then Dr. Dukes's argument as to the mutual unprotectiveness of the supposed new disease with scarlet fever on the one hand and with rose-rash on the other crumbles away; indeed, his whole case may be said to do so, for it should be specially noted that he records *no single case* in which this double mutual unprotectiveness was present.

Now, what are the facts? The first series of cases, we are told, resembled rose rash and were diagnosed by Dr. Dukes himself as such. We are not vouchsafed any information as to the clinical features of this particular series, therefore it is reasonable to suppose that they resembled ordinary cases of rose-rash in appearance, had little or no pyrexia, little or no throat affection, and, most important of all, did not desquamate as we usually understand the term. The same remarks apply to those cases of the second series which were not complicated with scarlet fever. All these cases, I suggest, were really rose-rash. Now compare with these the third series (occurring in March, 1900). Here we are told that the temperature ranged up to 104·2° F., that the fauces were red and swollen, that the eruption so closely resembled scarlet fever that nine out of 10 experts could not have distinguished it, and that desquamation was profuse. These are the cases which, I suggest, were scarlet fever.

If the first series of cases at all resembled these last ones, it is surely pertinent to ask how Dr. Dukes could possibly have diagnosed them as rose-rash rather than as scarlet fever. Under all the circumstances and with the very incomplete particulars forthcoming, it appears to me quite unreasonable to expect us to believe that all the cases were one and the same disease; much less that that disease was a new and hitherto unrecognised one.

As regards Mr. R. Leslie Romer, who gives in The Lancet of Nov. 17th (p. 1459) notes of a series of eight cases resembling scarlet fever but which he has now come to the conclusion were cases of "fourth disease," he says that the chief discrepancies between his cases and those of Dr. Dukes are (*a*) the different colour of the rash and (*b*) the fact that there was no coryza or any enlargement of the post-auricular glands. He appears to have overlooked the most important discrepancy of all—viz., that whilst none of his cases desquamated all those among Dr. Dukes's cases which resembled scarlet fever did so, some of them profusely. I would suggest, therefore, that Mr. Romer's cases were "fifth disease."—I am, Sirs, yours faithfully,

Burton-on-Trent, Nov. 20th, 1900. C. Killick Millard.

"THE TREATMENT OF MALARIA BY HOMŒOPATHIC MEASURES."

To the Editors of The Lancet.

Sirs,—I thank you for your courtesy in sending me a copy of The Lancet of Nov. 24th. Your doing so seems to imply that you expect from me some notice of your editorial referring to my paper before the Chamber of Commerce.[1] If you have sent one to Mr. Jones also perhaps he will be grateful for your unsolicited advice on his business matters, though I think I know him sufficiently well to be able to tell you that he will certainly, as you anticipate, "consider your view to be based upon narrow selfishness," and not only on narrow selfishness, but on wilful prejudice and blind bigotry. I am sure he will see through the sophistry of your assertion that "there is not such a thing as a qualified homœopathic medical man." He knows that such an assertion is a falsehood. He is also aware that you yourselves know very well that the expression "homœopathic medical man" means a medical man who practises homœopathicly; and that you know that the medical men who practise homœopathicly in this country are as legally qualified as you yourselves are. He also knows that it is not true that "medical men (*sic*) cannot work with homœopaths." It is well known to be a fact that consultations frequently take place between the best of the Liverpool traditional practitioners and the homœopathic practitioners of the city. You might have spared yourselves the snarling contrast between medical men and homœopaths, because it is too transparent for Liverpool merchants not to see through.

That the editors of an old medical journal should, at the end of the nineteenth century, assert that "homœopathy is based upon theories exactly contrary to medical knowledge" shows that medical editorial interests are stronger than the interests of truth. You ought to publish this reply; but, of course, in your editorial position you can refuse a reply to your wanton attack on homœopathy and your sophistical insinuations as to the status of medical men who practise homœopathicly, but if you do, there are other channels for exposing your unfairness.

I am, Sirs, yours faithfully,

Birkenhead, Nov. 24th, 1900. John W. Hayward.

*** The prevention and treatment of tropical disease are not Mr. A. L. Jones's business matters, though his generosity and energy are being excellently employed in assisting the interests of science. We repeat that "there is not such a thing as a qualified homœopathic medical man." There is no sophistry in our words. Homœopathic practitioners obtain their qualifications in medicine and surgery, and later become homœopaths. The insinuation that the qualifications upon which homœopaths have a place upon the Medical Register have been obtained by homœopathic work is more than a sophistry—it is a dishonest pretence. Mr. Parnell was a patriot according to his convictions, the idol of his followers, and the paramour of Mrs. O'Shea. But he was not the idol of his followers because he was the paramour of Mrs. O'Shea; and homœopaths are not on the Medical Register because of their therapeutic views. We do not know what a "traditional" practitioner is, but we shall be interested to receive proof that the leading medical men in Liverpool meet homœopaths in consultation. The exposure of our unfairness, as well as further correspondence on this subject generally, must be made in the "other channels" referred to; we can give no more space to the matter.—Ed. L.

THE INCUBATION OF PLAGUE.

To the Editors of The Lancet.

Sirs,—In connexion with the incubation period of plague the following case may be of interest. On Oct. 8th the senior warder at the Brisbane General Hospital assisted the Government medical officer at two post-mortem examinations of bodies subsequently proved to have died from plague. On the morning of Oct. 11th he complained of severe headache and had to leave his duties. On Oct. 12th it was proved both by clinical and bacteriological examination that the man was suffering from plague. He has several very painful buboes in the right axilla and numerous slight abrasions on his hands.

I am, Sirs, yours faithfully,

Harold J. Hutchens,

Medical Superintendent of the Plague Hospital.

Colmslie Hospital, Bulimba, Brisbane, Oct. 13th, 1900.

"THE USE OF TOBACCO ON ACTIVE SERVICE."

To the Editors of The Lancet.

Sirs,—The annotation on the above subject which appeared in The Lancet of Nov. 10th has attracted a considerable amount of attention. It seems to have been copied rather extensively by the daily press and has been freely and, for the most part, approvingly commented upon. Of course, in all matters relating to health the nation looks to the medical profession for advice and guidance. Now, as Lord Rosebery has recently said, the stability of a great empire like ours depends above all other things upon the health of the British people. It is, therefore, a matter of extreme importance that the advice which we give on this vitally important subject should be sound and unquestionable. This necessity is of all the greater importance in the case of those on whom the nation has to depend for its protection from its enemies.

It is owing to a sense of the serious responsibility involved that I venture to suggest that the writer of the annotation referred to, through a too hasty generalisation on the one hand and by overlooking more than one important fact on the other, has been led into serious error. He wishes your readers to believe that the use of tobacco on active service is productive of important advantages. In support of this view he makes this rather sweeping declaration in regard to the war in South Africa. "Perhaps nothing that it has demonstrated has been more marked than the important part which tobacco plays in the soldier's existence." He declares that "there can be no doubt about the truth of it." Yet the sentence which follows this positive declaration furnishes one of the strongest reasons for doubting its truth. We are told that "the Duke of Wellington's armies had no tobacco worth speaking of. If they did not forbid its use, at any rate the Iron Duke's officers were directed to advise their men strongly against it." Now is it for a moment likely that in Spain, where tobacco was cheap and plentiful and therefore easily supplied, the Duke would have discontinued its use if he had not had reason to believe that the army would rather be injured than benefited by the use of tobacco? Surely in order to justify the positive declaration which he makes the writer ought to have produced facts which would place the matter beyond doubt or dispute. But this he fails to do; his declaration is based on the flimsy ground of mere hearsay. But if we do not get facts we get opinions. We are told that "it is difficult to believe that tobacco is anything but a real help to men who are suffering long labours and receiving little food, and probably the way in which it helps is by quieting cerebration, for no one doubts its sedative qualities, and thus allowing more easily sleep which is so all-important when semi-starvation has to be endured." To this it is sufficient to reply that where healthy men have undergone severe fatigue in the open-air they will speedily sink into profound repose, when the fitting time arrives, and opportunity serves, however scanty the diet may have been. Where little or no exercise has been taken there may be unquiet cerebration, and tobacco may act as a sedative, but so will a few drops of tinct. opii or liq. mur. morph. But nature's supply is better than is that of art. The worn and weary man, in Shakespeare's words, "enjoys the honey heavy dew of slumbers," and rises on the morrow, bright and buoyant, ready to face cheerfully the toil and privation he may have to meet. But the man who has meddlesomely tampered with nature's kindly process awakes imperfectly refreshed, he is depressed, and is some time before he can shake off his languor. He has in no way benefited by his smoking; "the pipe did not 'ease the way to sleep,' and the sleep of the non-smoker was not delayed by sheer bodily fatigue and mental restlessness caused by prolonged and monotonous exertion."

---

[1] The Lancet, Nov. 24th, 1900, p. 1518.

Now, there are certain circumstances which your annotator has overlooked which render "the use of tobacco" very undesirable "on active service." 1. No fact is better established than that smoking is detrimental to good shooting. The best shots at Bisley are almost invariably non-smokers. 2. It is in the hours of idleness that smoking is most indulged in, and in proportion as it is indulged in the craving for it grows, so that the use in the vast majority of cases leads to the abuse. 3. The fumes of burning tobacco dry and irritate the fauces, exciting thirst, hence smoking and drinking generally are associated; discipline is in this way often infracted, and punishment frequently follows. 4. The fewer and the simpler the soldier's wants the better for his own comfort. The use of tobacco produces in the majority of cases an imperious want, and when it cannot be met the soldier is in great distress and his depression unfits him for earnest work.

I am, Sirs, yours faithfully,

Manchester, Nov. 19th, 1900. R. MARTIN.

"THE ETIOLOGY OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 27th there appears an open letter by Dr. Adolf Baginsky and Dr. Paul Sommerfeld supposedly in answer to an article published by me in THE LANCET of Sept. 29th. In this letter the above-mentioned gentlemen make the following statement: "Dr. Class must be ignorant of the customs of earnest Germans, and especially of our work, if he thinks that we wish to rob him of the merits of this investigation." I sincerely regret that Dr. Baginsky and Dr. Sommerfeld have misinterpreted my statements, as I did not have the slightest intention of accusing them of endeavouring to rob me of any credit, and am quite certain that if they had seen my contributions on the subject due credit would have been given by them. That they were not noticed shows, however, that Dr. Baginsky and Dr. Sommerfeld did not review American medical literature very carefully, as my work was published in the three leading American journals—namely, the *Journal of the American Medical Association*, the *Philadelphia Medical Journal*, and the *New York Medical Record*. I fully realise that it is almost impossible to review the entire medical literature of every country before publishing an article, still I believe if European investigation, especially those of continental Europe, would occasionally peruse our leading medical journals no harm would result to them beyond finding that some recent discoveries have been ante-dated by Americans. Dr. Baginsky and Dr. Sommerfeld further state in their letter that a possible point of difference between their germ and that described by me is that theirs occurs both as a diplococcus as well as a streptococcus. I am afraid that the gentlemen overlooked part of my description, as the variability in form mentioned by them was also given in my article. Before closing I wish to state that I am pleased to note that so distinguished a physician as Dr. Baginsky, whose work in pediatrics is fully recognised in this country, should have obtained results so closely agreeing with my observations. As we both have the same end in view—namely, to dispel the mystery surrounding one of the chief scourges of childhood—I can only wish him success in his further investigations.

I am, Sirs, yours faithfully,

Chicago, Nov. 18th, 1900. W. J. CLASS, M.D.

ETIOLOGY OF RHEUMATIC FEVER.

To the Editors of THE LANCET.

SIRS,—May I refer to my advertisement in THE LANCET of Nov. 17th and say that I should like a few more specimens of blood from rheumatic fever cases? In all those sent me the micrococci are present in the blood. Perhaps other members of the profession will kindly send me specimens. I am very pleased to send the cover-glasses and pay 2*s.* 6*d.* for the trouble and postage, as I am desirous of having a large number of specimens from all parts of the kingdom.—I am, Sirs, yours faithfully,

The Hall, Southwick, Brighton, Nov. 22nd, 1900. E. F. GRÜN.

DEW-PONDS.

To the Editors of THE LANCET.

SIRS,—Your annotation containing the result of experiments near the dew-ponds on the downs in THE LANCET of Oct. 13th is to me very interesting, inasmuch as the same condition appears to obtain in the Karoo veldt in the Cape Colony, and I can assure you one has plenty of time for contemplation amongst the scattered farms in the Karoo. The dams, as they are called, are quite shallow and yet retain water for long periods under a broiling sun, and this water serves for cattle, horses, goats, and Boers. I see no other explanation than that given by you.

I am, Sirs, yours faithfully,

Nov. 7th, 1900. BOER-BOK.

"ADJOURNED CORONERS' INQUESTS AND MEDICAL WITNESSES' FEES."

To the Editors of THE LANCET.

SIRS,—Section 22 of the Coroners Act, 1887, says:—

> A legally qualified medical practitioner ...... shall be entitled to receive such remuneration as follows; that is to say, (*a*) for attending to give evidence at any inquest whereat no post-mortem examination has been made by such practitioner, one guinea; and (*b*) for making a post-mortem examination of the body of the deceased, with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, two guineas.

The word which to my mind settles any dispute there may be as to the effect of these two subsections is the word "and" which connects them. If it had been intended that no more than two guineas should ever become payable the two subsections would have had the word "or" between them. Moreover, it cannot be argued that the evidence which the medical man would give under subsection (*b*) is covered by subsection (*a*), as the word "thereon" clearly refers to evidence which he is in a position to give after having made the post-mortem examination.

It seems clear to me that when a medical man is summoned in the first place merely to give such evidence as he can from his observation of the deceased he comes under subsection (*a*), and if that proves insufficient and he is told to make a post-mortem examination he does so under subsection (*b*), for which he is entitled to a further two guineas, but not until he has given the evidence which he is now in possession of, as the last words of the subsection show: "and for attending to give evidence *thereon*." The space at my disposal in Messrs. Burroughs and Wellcome's Medical Diary precludes me from entering at all fully into these and similar questions, but if carefully studied I believe in most cases the information given is sufficiently accurate to enable anyone to apply the argument for themselves. The text in this particular instance is a good instance in point.

I am, Sirs, yours faithfully,

THE AUTHOR

of A Brief Abstract of the Laws particularly applicable to the Medical Profession in Messrs. Burroughs and Wellcome's Medical Diary.

Nov. 26th, 1900.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Government Resolution on the Report on Plague in Calcutta.—The Progress of the Epidemic.—The Health Officer's Report on Malaria in Bombay.

A GOVERNMENT resolution on the report on plague in Calcutta has just been published. It gives a brief *résumé* of the leading points in the report of the chairman and makes some pertinent comments on certain facts recorded. The history of plague in Calcutta is now very stale news but whereas the official record dates the first outbreak from April, 1898, it seems very probable that the disease really existed in the city in 1896. It is recognised that the high general mortality in 1898 and in the first half of 1899 indicates a larger amount of plague than was shown by the official records. Just as in Bombay there is one ward which has stood pre-eminent for the number of its cases of plague. It is almost in the centre of the northern half of the town and its condition is most insanitary. Dr. W. J. Simpson described it "as unfit for habitation and a source of danger to the town. ...... The narrow ill-ventilated streets; the passages to which neither light nor fresh air have access; the filthy condition of both; the close proximity of the houses to one another and their overcrowded state combine to form conditions which render proper sanitation impossible. It is a standing menace to the rest of the city." The resolution refers to the various changes in plague policy which have from time to time been adopted, and says of the measures employed: "Of these the principal, in fact practically the only one, generally used in Calcutta has been disinfection." The difficulty of finding living cases of plague is drawn particular attention to, as very little help has been received from outside the plague department. In the second half of 1899 only 26 patients were seen alive, and while during the height of the outbreak in 1900 there were 1409 living cases seen out of 7897 reported, this absence of living cases is again noticeable since June 30th, 1900, and the resolution suggests, by certain quoted figures of mortality, that some 470 cases ending in recovery have escaped discovery and that a certain number of deaths really due to plague have escaped record as such. It seems impossible to avoid coming to the same conclusion. The wholesale or "extra-disinfections" are referred to with great confidence Up to Sept. 8th some 42,314 rooms have been subject to this "extra-disinfection." Since that date, I am informed, as many more have been treated, and that at the present time about 10,000 rooms are being disinfected every week. How far disinfection is efficacious in preventing the spread of plague is a question, therefore, to which the ensuing season will be likely to furnish an answer. The resolution implies that the result so far "is a decided if not conclusive preponderance of evidence that disinfection when carried out on as large a scale as possible is a useful and efficacious preventive agency." The Government has come to the conclusion that "disinfection is the only preventive measure which it is practicable to work on a large scale in Calcutta." With the exception of a paragraph referring solely to 1898 there is not a word mentioned about inoculation. The report concludes with an acknowledgment of the services rendered by the plague staff and by the few native gentlemen who have given some assistance.

It is evident that Calcutta has only had one serious outbreak of plague, as the estimated mortality for the two and a half years' period of the visitation only amounts to 13,000, of which 10,000 occurred this year.

For the whole of India there has been a slight decline in the number of deaths due to plague. For the week ending Nov. 3rd 2148 deaths were returned, as compared with 2174 for the previous seven days. In the Bombay Presidency there were 1123 deaths; in the Bengal Presidency, 278; and in the Mysore State, 737. The official returns for Calcutta show almost a blank, but I am informed that the apparent extinction is due to a different method of making the returns. A considerable number of suspicious deaths which were formerly included in the totals are now omitted. In Bombay city the disease is still smouldering. In Poona there is a decline, the deaths having fallen to less than 50 a day,

According to the health officer's report, investigations have been made in Bombay upon the localities in which the anopheles mosquito can be detected. More or less every part of the city and the island shows its existence, but it has been singled out especially at Malabar Hill; in the ravine on the west side of the reservoir and in the storm-water channel; in the pools on the Chowpaty estate on the east of Malabar Hill; in the Wellington and Floral fountains of the fort; and in the Bandora slaughter-houses and the Victoria Garden fountains. Malaria is said to have been more prevalent during the past few weeks. It is noted that in one compound on Malabar Hill nearly all the servants had malaria in some form or other, while the residents of the bungalow were free. Whether malaria has been more frequent of late or not is uncertain, but since the cholera outbreak subsided there has been little indication of decline in the general mortality. This shows a slight improvement during the past week, it is true, but the death-rate continues inordinately high. The excess mortality remains unexplained.

Nov. 8th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Poisoning by Beer.

THE existence of what has been called the "Manchester epidemic" is by this time widely known, as it has been very generally noticed in the papers. For some months past cases of what were generally considered to be alcoholic peripheral neuritis have occurred with remarkable frequency. Dr. E. S. Reynolds has seen great numbers at the workhouse hospital at Crumpsall and also at the Royal Infirmary, and he was one of the first to recognise the fact that they differed in some ways from typical cases of peripheral neuritis due solely to alcohol. Many others have noted the unusual prevalence of these cases in different parts of the city and surrounding district. One characteristic has been the frequent pigmentation of the skin, and in commenting on a case to the students at the infirmary Dr. J. Dreschfeld discussed the possibility of its being connected with arsenic. Dr. T. N. Kelynack has been observing these supposed cases of alcoholic poisoning for some time at the Pendleton branch of the Salford Royal Hospital and also at the Manchester Infirmary, and for the greater part of last week he was making investigations as to their cause in conjunction with Dr. R. Forsyth, medical officer to a large firm of brewers, and Mr. Kirkby, F.L.S., of the Pharmaceutical Department of Owens College. Arsenic was found by them in the beer, not from one, but from several breweries, confirming the results obtained by Dr. Reynolds and also by Professor Dixon Mann. Mr. C. H. Tattersall has also been making researches into the matter, and has sent various samples of beer to Professor Sheridan Delépine who found arsenic in them in considerable quantity. There seems to be no doubt that the source of the arsenic was the crude sulphuric acid used in the production of "invert" sugar supplied to certain manufacturers of cheap beer.

Manchester and Salford Sanitary Association.

At the meeting of the committee of the Manchester and Salford Sanitary Association held on Nov. 21st Professor Dixon Mann in the chair, Dr. F. J. H. Coutts was appointed medical honorary secretary in place of Dr. R. T. Williamson, resigned. At the request of the committee Mr. William Thomson undertook an investigation into the subject of lead-poisoning. He also presented a supplementary report on the recent cases of lamp explosion in Manchester and Salford He described the burners of the lamps and the flash-point of the oils used in them, five of the latter being of the Russian type and one of the American type "There had not yet been traced any explosion with an oil having a flash at or above 100° F." (!) The American type of oils, he explained, were those having flash-points between 73° and 79°, the Russian had the flash-point lying between 84° and 89°, while in the Scotch type it was at or above 100°, but that a certain American oil had also a flash-point of 100° or upwards.

The Lewis Epileptic Colony.

The David Lewis trustees have given nearly £100,000 for the establishment of an epileptic colony in Cheshire. A site has been obtained at Warford, between Knutsford and Chelford, where about 400 acres have been purchased. The patients will live in detached two-storey buildings, accommodating 20 or 24 inmates. The whole equipment, including an infirmary, recreation hall, administrative block, &c., will be on a liberal scale. Most of the food will be grown on the farm, and healthy occupation will be found for the patients.

Nov. 27th

SCOTLAND.

(From our own Correspondents.)

Dinner to the Edinburgh South African Hospital Staff.

On the evening of Nov. 23rd the members of the Edinburgh and East of Scotland Hospital staff were entertained to dinner in the Imperial Hotel by the Edinburgh Company of the Volunteer Medical Staff Corps. Surgeon-Captain Hepburn presided, and he was supported by Colonel Rooney, R.A.M.C., principal medical officer for Scotland; Surgeon-Captain Wallace, who was in charge of the hospital at Norval's Pont; Captain M'Intyre, and Mr. Hepburn. After the toast of "The Queen and Royal Family" had been honoured the chairman proposed "The Navy, Army, and Reserve Forces," and Colonel Rooney replied. The toast of "The Edinburgh South African Hospital" was then given by the chairman and was acknowledged by Mr. Wallace. Captain Erskine subsequently proposed the toast of "The Edinburgh Company." The members of the hospital staff have returned in good health, looking all the better for their South African experiences.

Edinburgh Royal Infirmary.

At a meeting of the managers of the Edinburgh Royal Infirmary on Nov. 19th the board, on the motion of Sir Andrew Macdonald, resolved to communicate with the Members of Parliament for the city, the county, and Leith, asking them to do all they could to support the Bill for exempting hospitals from local taxation The infirmary at present pays £300 in taxes.

Pharmaceutical Society of Great Britain.

The first evening meeting of the North British Branch of the Pharmaceutical Society of Great Britain was held on Nov. 23rd. Professor J. Arthur Thomson, Aberdeen University, gave the inaugural sessional address on "Medical Aspects of Natural History."

University of Edinburgh Preliminary Examination.

At the October preliminary examination in the Faculty of Medicine of the University of Edinburgh 128 candidates appeared for examination, of whom 13 were women. A large number of first-year students, however, are exempted from the preliminary examination by holding leaving certificates. The total number of first-year students of medicine, including extra-academical graduation women students, is 248.

St. Andrews Ambulance Association.

The annual meeting of the subscribers to the Edinburgh branch of the St. Andrews Ambulance Association was held on Nov. 22nd. In moving the adoption of the report Dr. P. A. Young, who presided, referred to the loss sustained by the association in the death of Professor Armstrong. Referring to the work of the past year, he said that the most important work had been the establishment and maintenance in South Africa of the Scottish National Red Cross Hospital. Between £40,000 and £50,000 had been subscribed for this scheme, and a hospital of 500 beds had been sent out which had won great praise from military men in South Africa With regard to the ordinary work of the association, it was worthy of notice that there had been a great increase in the number of removals by the wagons of the association. In the past year there had been an increase of 254 removals over the preceding year. He hoped that there would be an increase of contributions to enable them to keep up their work on the present scale.

Death of Deputy Surgeon-General Mackay.

Deputy Surgeon General George Mackay, M.D. Edin., J.P., died at his residence in Edinburgh on Nov 20th. Deceased was the eldest son of the late Major Donald Mackay, of the 70th Foot and grandson of Colonel George Mackay, of Boghouse, Sutherlandshire. He was born in 1820 and in 1841 took the degree of M.D. at the University of Edinburgh, when he also became a Licentiate of the Royal College of Surgeons of Edinburgh. In 1842 he received a commission in the medical department of the Honourable East India Company's service. He took part in the operations against the Mahrattas in 1844. He was in active service in Burmah in 1852 and received the medal and clasp for Pegu. After the war he returned to Madras and officiated as civil surgeon, first at Coimbatore and later at Ootacamund. In 1854 he was promoted to the rank of surgeon-major and was transferred to the Military Finance Department as examiner of medical accounts. Subsequently to this he became secretary to the Madras Medical Fund and the Military Fund. He retired from the service in 1875. He is survived by his widow, three sons and three daughters.

New Veterinary College.

Professor W. Owen Williams has succeeded his father as principal of the New Veterinary College, Edinburgh.

University of Aberdeen.

All the property needed for the erection of the new Greyfriars Church having now been acquired, Mr. A. Marshall Mackenzie, A.R S A., Aberdeen, has been appointed to prepare plans for the new building, and it is understood that an ornate front for Marischal College extension is being kept in view in prospect of the removal of the old church and other buildings in the Broad street front.—The University Court have declined to make any alteration in the arrangement as to matriculation fees.—The Students' Representative Council has received a letter from Mr. J. E. Crombie, Lord Rector's assessor at the University Court, promising to further the erection of a gymnasium for the University.

Aberdeen Royal Infirmary.

Dr. Robert John Garden having resigned his post as senior surgeon Dr. John Marnoch has been appointed one of the the surgeons, and applicants for the vacancy in the assistant surgeonship caused by Dr Marnoch's promotion will be advertised for. The employés of the municipal corporation still refuse to contribute systematically to the infirmary, but another effort is to be made to get them to reconsider their position.

Nov. 28th

IRELAND.

(From our own Correspondents.)

The Banquet at the Royal College of Surgeons in Ireland.

The welcome-home dinner given by the Royal College of Surgeons in Ireland to the medical staff of the Irish Hospital recently returned from South Africa took place on Nov. 24th and was a very great success. Between the Fellows of the College and their guests about 150 were present, including his Excellency the Lord Lieutenant of Ireland, the Lord Chancellor of Ireland, the Right Hon. G. Wyndham, M P., Chief Secretary for Ireland, Lord Iveagh, M.P., the Right Hon. the Attorney-General, M.P., and Lord Plunket. The President of the College, Dr. Thomas Myles, occupied the chair, and after the health of Her Majesty the Queen was duly honoured he mentioned that His Royal Highness the Duke of Connaught had authorised him to state that he much regretted to find that he was unable to attend on account of another engagement Lord Cadogan, though still suffering from the effects of his recent accident and obliged to walk with the assistance of two sticks, delivered a most interesting and admirable speech after he had read with dramatic effect a telegram of congratulation and of welcome to Sir William Thomson and his staff from Her Majesty the Queen.

Death of Dr. Francis J. B Quinlan.

A brief notice appeared in THE LANCET of Nov. 17th, p. 1465, of the death of Dr. Francis J. B. Quinlan, who was known for many years in Dublin as physician, medical teacher, examiner, and professor. His funeral, which took place on Nov. 12th, was largely attended by his brother Fellows of the Royal College of Physicians of Ireland and by a representative gathering of the medical profession generally. Some 15 years ago he was much engaged in private practice, but being from the money point of view independent he gradually gave up the occupation of a popular physician in order to devote all his energies to the teaching of his favourite subjects—materia medica and therapeutics. Since the foundation of the Royal University of Ireland he was the Dublin examiner in those subjects there, while he also held for years the post of examiner for the Conjoint Board of the Royal College of Physicians of Ireland and of the Royal College of Surgeons in Ireland. He was, in point of fact, for years the most eminent and widely known teacher in Ireland in the subject which he had made his own. For the last quarter of a century he filled the office of professor of materia medica at the Catholic University Medical School, while to all students of that school, as well as to those of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, and also to those of the Royal University of Ireland he was well known as an examiner. From his position as a professor and teacher during so many years his personality was familiar to crowds of students of medicine now in practice and to readers of THE LANCET all over the world. They will recognise the void which his rather sudden death has left in the ranks of the lecturing and teaching medical professors of Dublin. Like his father, who was a well-known citizen of Dublin and editor of a daily journal Dr. Quinlan possessed much literary ability and he frequently contributed admirable articles on Public Health and Hygiene to the *Irish Times* as well as to the medical journals. Although he was a prominent professor in the medical school of the Catholic University, Dr. Quinlan was always in politics a strong Unionist, a consistent Conservative, and an active member of the Senate of the University of Dublin. He had passed his seventh decade, but up to the last few weeks was a most energetic and effective lecturer and teacher. His rather sudden breakdown in health and subsequent death was thus a disagreeable surprise to his wide circle of friends.

Nov. 28th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Mercantile Marine Medical Officers.

A DISPUTE arose recently between the medical officers of the mercantile marine and the head of the Sanitary Department of Marseilles. The former are employed by the great steamboat companies and travel on their boats; the Sanitary Department is an official body connected with the Public Health Department and consequently is under the Minister of the Interior. The ships' medical officers have charge of the passengers and crew and attend them when they are ill during the voyage They must also on the arrival of a ship in port hand in a statement as to the health of the ship. None the less, however, the port medical officer makes an official visit and he alone decides as to what, if any, measures of disinfection have to be taken with regard to passengers, crew, cargo, or boat This independence of the two services is absolutely necessary, for the ship's medical officer, who is in the employ of the company, is liable to lose his place if he shows himself too severe or inflicts losses on the company by keeping the ship at a loss in quarantine. On the other hand, the port medical officer, whose duty it is to inspect steamers, often carrying from 700 to 800 souls, is very wide awake to the enormous responsibility which devolves upon him if he lets pass one single case which may become the focus of an epidemic, and is consequently liable to be over-exacting. Hence arises friction which recently culminated in actual conflict. The Maritime Medical Society at a recent meeting passed a resolution, which was published in the press, that its members had decided to have nothing more to do with the port sanitary authorities at Marseilles and they also protested against the little regard shown to themselves by the sanitary authorities who looked upon them with suspicion. They also protested against the very insufficient measures of disinfection which are taken at the sanitary station of Frioul in the case of ships coming from infected ports. They instanced the case of a steamer from Senegal, one of the officers of which, who had been confined in the sanitary station at Frioul, escaped during the night with the complicity of the sentry and was out for several hours. This protestation, which is somewhat contradictory in that at the same time it complains of over-strictness as regards certificates and of laxity as regards the disinfection of ships, has called forth an answer in the form of a letter from the chief of the Sanitary Department to the Minister of the Interior, but it seems likely that matters will quiet down. Certainly the port sanitary authorities should pay every attention to the certificates given by ships' medical officers; but, on the other hand, there have been too many instances in which these officers have shown regrettable laxity in the interests of their company, from fear of losing their posts. The remedy would seem to be that the ships' medical officers should be independent of the companies in whose service they are and should be appointed by the State, as are the inspectors of sugar refineries, petroleum distilleries, and other industrial establishments which inspectors have to watch in the interests of the public purse, but where, nevertheless, the owners have to pay the inspectors.

Military Service for Medical Students.

The position of medical students in France from the point of view of military service has for a long time past given rise to criticism. Formerly, when the "voluntary year" of service existed they did very well on the whole. They were allowed, on payment of 1500 francs, to serve for only one year instead of for five years, as all other classes of Frenchmen between the ages of 20 and 25 years had to do except in a few cases, such as the son of a widow. Between the ages of 25 and 45 years they were enrolled, as all other soldiers, in the army of the reserve, and after that in the territorial army, which is never called up except in case of war, save only for the manœuvres. As for the year passed in barracks medical students were, as a rule, if they wished it, attached to a regiment of hospital orderlies as simple privates. In the army of the reserve and in the territorial army they ranked as assistant surgeons (*médecins auxiliaires*)—that is to say, as non-commissioned officers, and once they had taken the degree of doctor they ranked as *médecins aides-majors*—namely, as officers, and in the event of war had to do the same work as regular military surgeons. Under these conditions it was only to be expected that the year passed in barracks would have been devoted to instructing the student in the work which he might have to do as a *médecin aide-major*, including besides purely professional and administrative details such as the organisation of hospitals. What happened, however, was the exact contrary. The student received no instruction on these matters, but was treated as an ordinary private, no difference being made between him and a peasant who was probably destined to be never anything more than a simple orderly. When, moreover, men had to be chosen from among these orderlies for work in military hospitals the ordinary private was always chosen in preference to the medical student, who was kept at work in the barracks sweeping out courtyards, washing vegetables, or being employed on sentry-go and picket duty. The majority of medical men in Paris at the present time have passed through a "voluntary year" of this kind. The fact, however, is capable of explanation up to a certain point, for it was necessary that orderlies should have some instruction in their duties, however humble, as regards the sick, for the medical student during war-time would not be acting as an orderly but as a surgeon. But the medical student should certainly have been instructed during his year of service in his possible future duties as regards ambulance work and the like. This instruction was only given during the period of the manœuvres, which lasted too short a time to make the instruction really of use. The recruiting law of 1889 brought no real change. True, the "voluntary year" was abolished and the term of compulsory service was reduced from five years to three; medical students in common with those of other liberal professions passed only one year in barracks, but they had to be fully qualified by the age of 26 years. If they were not, they had to complete the remaining two years of military service, so that the only way in which the medical student benefited by the law of 1889 was that he no longer had to pay the 1500 francs for the privilege of only serving one year. As to his work during this year, the most diverse regulations existed in different regiments. Some students were attached to an orderly regiment and kept at work in barracks, some passed six months as hospital orderlies and some were attached to an ordinary regiment and were treated exactly like ordinary privates. In what way the student was employed rested very much with the colonel of the regiment. To remedy these defects two propositions have just been laid before the Chamber—one by M. Lachaud, providing that all medical students should be considered as real *médecins auxiliaires* from the time of their joining the regiment after a very short course of military instruction. The other, presented by M. Astier, goes further and suggests that service for one year should be done away with, for he considers, with a certain amount of reason, that to this is due the overplus of medical men. For the one year's service instead of three attracts a great number of young men to enter the medical profession. The Government has, however, issued a decree which closely approaches the proposal formulated by M. Lachaud. Medical students will continue to put in only one year of military service, but after six weeks' military instruction they will be employed as *médecins auxiliaires.* This solution of the difficulty, which is generally regarded as satisfactory, is partly owing to the fact that the army is very short of medical men. The authorities do not want to increase the number at present on account of expense, neither do the present military surgeons want their numbers increased, for promotion is slow enough as it is However, the new regulation pleases nearly everyone. The number of *médecins militaires* will be greatly increased even on a peace footing without extra expense, and the students will still have to serve only one year, and that under more agreeable circumstances than formerly, and will receive more thorough instruction as to their possible duties in time of war. There is one defect in the regulation and that is that no mention is made as to when in his medical course the student is to serve his year. Most students will certainly try to get it over as soon as possible—that is to say, at the beginning of their medical course. They will therefore give their military service at a time when they have had practically no medical instruction whatever and so will be of very little use. It would have been much better if the year of service had been made compulsory at the end of the medical curriculum when the student could have rendered service both to the army and to his profession. The young medical man should certainly be sent for his year to a provincial garrison, and thus the overcrowding of the great centres with medical men would be avoided.

Obituary.

The death of Professor Ollier at Lyons is announced. He was in his seventieth year and was professor of clinical surgery at the Faculty of Lyons, a corresponding member of the Institute, and Commander of the Legion of Honour. He was well-known by his work on resections of bones and joints. It was he who attended President Carnot after he received the knife-blow which proved fatal. Professor Ollier was made honorary Fellow of the Royal College of Surgeons of England at the recent centenary.

Obituary.

RICHARD NEALE, M.D. LOND., M.R.C.S. ENG., L.S.A.

DR. RICHARD NEALE, who died on Nov. 22nd at the age of 73 years, was a great benefactor to the medical profession by reason of his having inaugurated and conducted the well-known "Medical Digest" He received his medical education at University College Hospital He took an interest in the purification of air by chemical means and was the inventor of an apparatus which he wished to be tried upon the Underground Railway for this purpose. The apparatus was described in THE LANCET of August 1st (p 301) and 8th (p. 359), 1880, but we do not think that it ever came into practical use. Dr. Neale's life-work, however, was the "Medical Digest," a work of incomparable usefulness. The latest edition contains references to the most important British medical periodicals from 1840 to the beginning of 1899. We can say for ourselves that we have rarely, if ever, known the "Digest" to fail in giving the information which we have sought in its pages, and our frequent quotations from it for the benefit of our readers show its worth. We have often wondered why correspondents write to us asking us questions, the exact answers to which will be found in so well-known a volume. In an out-of-the-way part of the country we can understand the practitioner deciding that the possession of an index to literature which he cannot consult is of no practical use to him; but where files and bound volumes of all good medical periodicals can be perused—as obtains in every big town in the land—no medical man will regret the purchase of a "Digest." Armed with it he is master of all possible information on medical periodical literature. Although the price of the book (25*s.* 6*d*) seemed high Dr. Neale made nothing by its sale, and yet he worked at it for four hours a day during 50 years. In recognition of his unselfish labours a testimonial was set on foot, being the outcome of an appeal signed by leading members of the profession which appeared in THE LANCET of Feb. 10th, 1900 (p. 420), and a list of subscriptions received appeared in THE LANCET of May 5th last, (p. 1335). It is most earnestly to be hoped that some one will be found who will take up the work which Dr. Neale can no longer carry on, for it would be a thousand pities if such a useful compilation were to come to an end.

JOSEPH MORTIMER GRANVILLE, M.D. ST. AND., M.R.C.P. LOND., M.R.C.S. ENG.

WE regret to have to record the death of Dr. Joseph Mortimer Granville which took place on Nov. 23rd at 7, Queen Anne-street, Cavendish-square. Dr. Mortimer Granville was 67 years of age at the time of his decease. He was at one time associated—in the capacity of editor, we believe—with the *Globe* and subsequently was connected with this journal, having been many years ago a member of the staff of THE LANCET. Dr. Mortimer Granville had many marked qualifications as a journalist which had been cultivated and developed by much literary work in that capacity. He was a voluminous reader and had an alert and retentive memory. He possessed an easy and facile style and considerable power of rapid and varied composition. Combined with this he had a fresh and novel way of viewing a great variety of subjects which came within his purview. He was rather to be regarded as a conversationalist with a pen in his hand than as a patient, clear, and accurate thinker, but if his mental promptitude was occasionally wont to capture his judgment he was, nevertheless, often able to prick his readers' ears with an apparent paradox or impart some fresh and suggestive view to their minds. It was more particularly in writing upon current events of a socio-medical, clinical, or mixed character and of a more or less ephemeral interest, where he could rapidly focus the results of his previous reading or those derived from an unconscious exercise of memory, and mingle them with his own ideas, that Dr. Mortimer Granville was at his journalistic best. We do not think that, notwithstanding his undoubted ability, his friends and admirers would claim for him that he was to be ranked as a scientific type of worker. Having ceased connexion with this journal he continued to practise in London as a physician and wrote much on various subjects of a more or less professional character, especially in regard to gout, on which, it is needless to add, he entertained very different views to those held by medical authorities generally. He published various small treatises of a popular sort which displayed his talent for shrewd, if superficial, observation Among these may be mentioned "Minds and Moods," "Sleep and Sleeplessness," "The Secret of a Clear Head," and "The Secret of a Good Memory," all of which were designed to popularise knowledge of common psychological phenomena. His interest in mental problems was undoubtedly stimulated by work which he had done in our columns when making as our Commission certain inquiries into the care of the insane The results of the investigations which he then undertook were afterwards published under his name with the title "The Care and Cure of the Insane," and they constitute his only work upon mental disease and allied subjects having any pretence to scientific scope. He also wrote largely upon gout, and invented various small instruments, such as surface and differential thermometers, designed for medical use. Dr. Mortimer Granville became M.R.C.S. Eng. in 1856, M.D.

St. And. in 1876, and M.R.C.P. Lond. in 1883, and was a member of several societies.

ROGER EDWARDS, M.D. DURH., L.R.C.P. LOND., M.R.C.S. ENG.

DR. ROGER EDWARDS died at his residence, Colwyn Bay, North Wales, on Nov. 21st, in his fifty-first year. Dr. Edwards, who was born at Dolgelly, received his medical education at University College Hospital, London, and qualified L.R.C.P. Lond. and M.R.C.S. Eng. in 1875 and in 1896 he graduated M.D. of Durham University. After holding resident appointments at University College Hospital and the Royal Free Hospital Dr. Edwards settled at Llanfyllin, Montgomeryshire, where he soon established an extensive practice. The deceased was formerly medical officer of health for the Bala Urban District Council. He took a great interest in municipal matters and was several times re-elected mayor of Llanfyllin. Dr. Edwards was also a member of the Montgomeryshire County Council and chairman of the county governing body.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Edward R. Squibb, a well-known pharmacologist. He had in early life been in medical practice. His "Ephemeris of Materia Medica" is well known.—Dr. Karl Georg Gaedeken, Professor of Medicine, Hygiene, and Mental Diseases in the University of Copenhagen.—Dr. Hugo Bergeat, a well-known Munich laryngologist.—Dr. George Stetter, Professor in the University of Königsberg. He was chiefly known by his writings on fractures and dislocations. He was 52 years of age.—Dr. Antonio Ferreira França, formerly Professor of External Pathology in the University of Rio de Janeiro.—Dr. Moses White, formerly Professor of Pathological Anatomy in Yale.—Dr. F. Acconci, Professor of Gynæcology in the Medical School of Genoa.

THE ANNUAL DINNER OF THE BRISTOL MEDICAL STUDENTS.—On Nov. 22nd, the Bristol medical students held their annual dinner under the presidency of Dr. Shingleton Smith, at which Sir William Broadbent was the guest of the evening. About 110 gentlemen were present, including for the most part past and present students and local practitioners. After dinner the president proposed the first toast, that of "The Queen and Royal Family," and reminded his hearers that it was only just over a year since Her Majesty had so graciously come down to open the Bristol Convalescent Home. After a verse of "God save the Queen" the guest's health was drunk with musical honours. Sir William Broadbent responded in a few words. Mr. C. E. S. Flemming then proposed "The Army, Navy, and Auxiliary Forces," and Surgeon-Major D. S. Davies replied. Sir William Broadbent then rose to propose the "Health of the Bristol Medical School" and said that he felt that the chief right he had in proposing this toast was that he felt so much sympathy with it and that he wished well for the school. He had constantly heard of the Bristol Medical School throughout his life, and he thought that its incorporation with University College was but a stepping-stone to a Bristol University. He said he thought that the clinical practices of the Bristol Royal Infirmary, the Bristol General Hospital, the Eye Hospital, and the Children's Hospital, which were all open to students, combined to form a field for clinical work and observation which would make such an institution a formidable competitor in the teaching world of medicine and might even, he thought, attract students from London. In conclusion, he said that he wished success to the faculty, to the students, and to the medical school. Dr. Markham Skerritt, who replied for the Bristol Medical School, said that he hoped in regard to a university that they would follow in the steps of the inhabitants of Birmingham, who had taken time by the forelock and had constituted their university at a time when a race had not arisen which "knew not Joseph." He thanked Sir William Broadbent for coming among them and speaking in such kind terms of University College. Dr. A Ogilvy then proposed the toast of the "Past and Present Students" and Dr. Weatherly and Mr. Corfield replied. This was followed by the toast of "The President," proposed by Dr. Doyne, and to this Dr. Shingleton Smith replied. The toasts were interspersed with music and songs, and on the whole this was one of the most successful dinners that has yet taken place.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE seventieth session of the General Council of Medical Education and Registration was opened on Tuesday, Nov. 27th, the President, Sir William Turner, being in the chair. The programme of this session, it was expected, would be got through by Saturday (to-day), and there are financial reasons for curtailing the sessions of the Council. This forecast, however, is already discredited, for the Council has fixed the hearing of a very important case of a disciplinary character for Monday, Dec. 3rd. It looks as if the adjustment of the expenditure and income of the Council will have to be secured by other means than by reduction in the number of days of the sessions.

The members of the Council arrived in due time and in full force, including Sir William Thomson of Dublin, to whose services in South Africa the President made an eloquent allusion which was heartily cheered by the Council. The three new members—Professor B. C. A. Windle, representing the University of Birmingham; Professor Charles Bent Ball, the Royal College of Surgeons in Ireland; and Professor Alfred Harry Young, the Council of the Victoria University—were duly introduced. The resignation of Sir Philip Smyly created a vacancy in the Executive Committee to fill which the Council elected Sir Christopher Nixon.

The address of the President consisted largely of highly appreciative notices of the late Sir Henry Acland, Dr. Dennis Embleton, and Professor D. J. Leech. The two former were among the original members of the Council; and few members have been more regretted than Professor Leech, whose services, especially in the matter of the Pharmacopœia, were most valuable. Sir William Turner touched with much judgment and good taste on the thorny subject of the right of the Council to "approve" the institutions, schools especially, whose examinations in chemistry, physics, and biology are accepted by the Royal Colleges of England, and drew forth the applause of the Council when he expressed the hope that differences between the Colleges and the Council would be settled without a breach of that good understanding which had done so much for medical education in the past.

A highly interesting communication transmitted from the Foreign Office was read from Mr. William Wyndham, Her Britannic Majesty's Consul at Chicago, with reference to a bogus diploma mill in that city. Mr. Wyndham stated that an Englishman named Allan Fisher is selling in England the medical degrees of the People's Institute, an association which has been raided by the Chicago police as fraudulent. Mr. Wyndham gave the names of certain persons known to have purchased these sham medical degrees, and we are glad to believe none of the persons are on the Medical Register.

The proceedings on Wednesday afternoon formed an illustration of a way that the Council has of raising again and again the same question, and of devoting hours to the discussion of it, only to arrive at an infinitesimal change of result in no way justifying the expenditure of the Council's time and money. If there was one thing which the Council had discussed thoroughly, it was the question of the curriculum and the examinations for diplomas of Public Health. The subject was dealt with by Sir John Simon before he left the Council, and his voice was most influential in such matters. His interest in that subject was great for two reasons—first, the intrinsic importance of it; and, secondly, and more particularly, because the Medical Act of 1886 had given to the General Medical Council much responsibility in the matter, providing that the registration of any diploma in sanitary science shall be dependent on the discretion of the Council. But two years ago Sir William Gairdner called attention to apparent diversities of interpretation of the Council's regulations concerning diplomas in Public Health that prevailed in different localities, with the result that the Public Health Committee was instructed to inquire into the matter. This committee presented on Wednesday a lengthy report, to which we refer our readers. Sir John Batty Tuke moved, as an amendment to the formal motion of Mr. Teale that his committee's report should be received and entered on the minutes, that the report be re-committed, on the ground that the Council, if it followed the recommendation of the committee, would be lowering the status of the diplomas. The amendment was lost and the report was debated at length by the Council in committee without any appreciable alteration being effected in existing regulations.

TUESDAY, NOV. 27TH.

The seventieth session of the General Council of Medical Education and Registration was opened to-day, the place of meeting being the hall of the Council in Oxford-street, London. The President, Sir WILLIAM TURNER, occupied the chair.

Introduction of New Members.

This was the first business of the session. There were three Members to introduce. Dr. MacAlister introduced Dr. Bertram C. A. Windle, the first representative of the University of Birmingham; Dr. Bennett introduced Dr. Charles Bent Ball, the successor of Sir Philip Smyly in the representation of the Royal College of Surgeons in Ireland; and Sir Dyce Duckworth introduced Professor Alfred Harry Young, who succeeds the late Dr. Leech in the representation of the Victoria University.

Presidential Address.

The PRESIDENT then delivered his address.

The Deaths of Sir Henry Acland, Dr. Leech, and Dr. Embleton.

The PRESIDENT said that he would be wanting in respect to the memory of one of the most eminent of his predecessors if he were to open the present session without referring to the death, a little more than a month ago, of one who for 13 years occupied the presidential chair of that Council. Sir Henry W. Acland was chosen by the University of Oxford as its representative when the Council was formed in 1858, and he and Dr. Dennis Embleton, whose death was announced a few days ago, were the last of the eminent men who constituted the first Council of Medical Education and Registration. At Oxford Sir Henry Acland was prominent in the establishment of the museum as a great centre of scientific training, in the extension of the Professoriate, and in the encouragement of scientific studies as avenues to obtaining degrees in Arts and Medicine. During 29 years he sat in this Council as one of its members. Dignified in presence, courteous in manner, graceful in speech, he brought to bear on the consideration of their business a cultivated and reflective mind. His life and environment led him fully to appreciate the position of medicine as one of the learned professions, and that the special technical training necessary for its efficient practice should be based on a sound general and scientific education. His academic and social position and the innate nobility of his nature had from an early period of his life gained for him the friendship and confidence of the leaders of the medical profession, of statesmen of both parties, and others eminent in public life, and contributed in no small measure to insure the Council's harmonious relations with the departments of Government with which it was officially brought into communication. To the late Dr. Leech the Council was greatly indebted for skilful guidance in the preparation of the last edition of the Pharmacopœia, and of the Indian and Colonial supplement, with the latter of which he was engaged almost to the end. Dr. Leech had bequeathed to the Council for its library a valuable collection of Pharmacopœias and other volumes bearing on his special subject. The Victoria University had chosen as his successor Professor A. H. Young, M.B. Edin., of the Owens College. Sir Philip Smyly had resigned his seat as the representative of the Royal College of Surgeons in Ireland and the College had elected Dr. Charles Bent Ball.

University of Birmingham.

"On May 25th of this year," the President continued, "an Act passed the Legislature granting to the University of Birmingham, which had been established by Royal Charter on March 24th, the power to hold qualifying examinations in medicine, surgery, and midwifery, for the purpose of registration under the Medical Acts, as if it had been a University in the United Kingdom legally qualified at the date of the Medical Act, 1886, to grant diplomas in medicine and surgery. The Council of the University also became entitled to choose one representative to be a member of the General Medical Council as if that University had been included in Section 7 of the Medical Act, 1886. On June 20th of this year I received official intimation of the passing of the Act and requested the Registrar, as soon as copies could be obtained, to forward one to each member of the Council. Section 2 provided that the Act was to come into operation on Oct. 1st, and on Oct. 4th the Vice-Chancellor intimated that Dr. Bertram C. A. Windle had been chosen as the representative of the University of Birmingham. This Act of the Legislature has given an additional member to the Council, and in choosing Dr. Windle the University has selected a member who has long been engaged in medical education, on the details of which he can speak from personal knowledge and experience.

Bills in Parliament.

During the last session of Parliament three Bills were before the House of Commons on subjects in which the Council was interested. A Bill for obtaining additional penal and disciplinary powers over registered medical practitioners was read a first time, but as it was introduced late in the session it made no progress. I propose to make arrangements for the introduction of the Bill as soon as Parliament meets for the transaction of general business. In the Companies Acts Amendment Bill Clause 3 made it unlawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife. The Bill passed the second reading and subsequent stages, but the clause appertaining to the medical profession was struck out in the committee of the House of Commons. The Midwives Bill, to the consideration of which the Council had devoted much attention and which was partially debated in the Commons, became a dropped measure.

The Royal Colleges of Physicians and Surgeons in London.

On the last day of the May session I undertook to obtain the opinion of our legal advisers on the legal questions raised in the report of the Education Committee on the subject in dispute between the Council and the Royal Colleges of Physicians and Surgeons in London, and the representatives of those Colleges promised to endeavour to obtain certain additional information bearing on the question. Through these gentlemen and the courtesy of the President of the Royal College of Physicians the opportunity was given to me to bring the case, drawn on behalf of that College, and the opinion of their counsel thereon, before Mr. Muir Mackenzie, along with the resolutions of the Council and the reports of the Education Committee. These papers have been considered by our counsel during the recess and he has written his opinion which, as a confidential document, will be placed in the hands of members of Council.

The Apothecaries' Hall, Dublin.

Intimation has been given to the Council that the Examining Board in Ireland, formed by the combination of the Royal College of Surgeons and the Apothecaries' Hall, has been dissolved. The Examination Committee will report on inspections of the Third and Final Professional Examinations of the Apothecaries' Hall, Dublin. Dr. G. A. Gibson, who has acted as the Council's inspector of the examinations of this body for two years, has intimated to me his resignation. As he has discharged his duties with great care and judgment the Council will, I hope, give me authority to express our thanks to him for his services."

Dr. MACALISTER moved that the Council thank the President for his address and request him to allow its being printed in the minutes, and in doing so he said he desired to associate himself very warmly with all that Sir William Turner had said about their late colleague, Dr. Leech.

Mr. BRYANT seconded the motion, which was at once agreed to by the Council.

The Service Examination Results.

The REGISTRAR (Mr. H. E. ALLEN) presented two tables, one showing the results of the competition held on July 27th for commissions in the medical staff of the Royal Navy and the other showing those of the competition held in August for commissions in the medical staff of the Army.

Dr HERON WATSON, seconded by Sir DYCE DUCKWORTH, moved:—

> That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy and to the Director-General of the Army Medical Service for the returns which they have respectively again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council.

This motion was agreed to.

Dr. BRUCE moved that the tables be referred to the Examination Committee for their consideration. These tables, he said, contained valuable matter and were not in his opinion sufficiently considered.

Mr. BROWN, in seconding this motion, called attention to the large number of rejections in the Army examination.

Sir DYCE DUCKWORTH, chairman of the Examination Committee, opposed the motion on the ground that the tables spoke for themselves and his committee could do nothing with them. The subjects to which Mr. Brown had referred to were not strictly medical subjects. They were subjects intended to test the general culture of the candidate, such a subject, for instance, as physical geography. Most members were aware of the difficulties at present in securing candidates of a high class for the army and he need not go into them. As to the navy he, as an old examiner, was able to say that the condition of the medical service was most satisfactory as regards the quality and high standing of the men who applied and were appointed to it. As chairman of the Examination Committee he must decline the proposed task.

Dr. MCVAIL said that he was a member of the Examination Committee and he thought that these tables should be submitted to it. In the case of the army examination it appeared that there were 50 vacancies offered for competition, that 15 men came forward, and that only nine of them got appointments. It was well known that the army could not get the necessary supply of surgeons. So much had that been the case that the War Department had given nominations for places without examination at all to various universities and corporations. It would seem, therefore, that the rejected candidates or the candidates who did not receive appointments at this examination must have been sadly incompetent and he thought that that was a matter for inquiry. If, as Sir Dyce Duckworth said, the insufficiency was in subjects not strictly medical then this Council ought to know it. This Council had of course nothing to do with physical geography. What this Council had to see was that men getting diplomas from the various universities and corporations were competent in the subjects recommended by the Council.

The motion to refer the tables to the Examination Committee was carried by 11 to 10 votes.

Procedure in Dental Penal Cases.

On the recommendation of the Executive Committee the Council adopted certain amended standing orders relating to dental penal procedure The principal object of the amendments made is to enable the Council to do what it frequently does in medical cases, postpone the final judgment after deciding that the charge is proved.

Vacancy in the Executive Committee.

Sir Christopher Nixon was appointed to fill the vacancy in the Executive Committee due to the resignation of Sir Philip Smyly.

Pharmacopœia Committee.

Dr. MACALISTER brought up the following report from the Pharmacopœia Committee:—

> The Pharmacopœia Committee, in common with the whole Council, have to lament the loss they have sustained by the untimely death of Dr. Leech. As an active member of the committee since 1892, and as their chairman since 1893, he rendered zealous and valuable service in the preparation of the British Pharmacopœia, 1898, and of the Indian and Colonial Addendum. A special record of the committee's indebtedness to him was made in their report to the Council of May 31st, 1898 He also brought about the establishment of a regular conference between representatives of the committee and of the pharmaceutical societies of Great Britain and of Ireland for the investigation of questions bearing on the revision of the Pharmacopœia. At the suggestion of this conference a number of important researches have been begun, and some, notably those of Professor H. G. Greenish on the solubilities of official drugs, have in part been published. Such researches will be of material assistance to the committee in the task of revising the Pharmacopœia and will serve to carry forward the work in which Dr. Leech took so deep and effective an interest. His portrait, presented by a member of the committee, has been placed in the committee room.
>
> The committee have elected Dr. MacAlister to be chairman in the place of Dr. Leech.
>
> Up to the present the number of copies of the British Pharmacopœia, 1893, printed for the Council has been 31,500. Of these 29,840 have been disposed of, leaving a balance of 1660 copies in hand. The number sold in the present year up to Nov. 24th was 2003. As the publication of the Addendum will probably increase the demand for copies of the Pharmacopœia, to bind up with it, the committee recommend that the President be authorised to direct the printing of an additional issue of 1500 copies, should this appear to be necessary before the next meeting of the Council.
>
> The committee have met repeatedly during the recess for the purpose of completing the draft of the Indian and Colonial Addendum, 1900, which forms the subject of a separate report.
>
> During this work the need of a reference collection of medicinal plants and other articles of materia medica has more than once been felt when questions of description or identification were under discussion. The nucleus of such a collection already exists in the specimens forwarded by some of the colonial authorities. The committee ask power to make the collection complete and to furnish the committee room with proper cases for its reception.
>
> Donations of books for the reference library have been made by Mrs. Leech and Dr. Attfield, to whom the thanks of the Council are due. Dr. Payne has undertaken the duty of supervising the arrangement and cataloguing of the library, which now contains a number of rare and interesting works.

In moving the adoption of the report Dr. MACALISTER said that he learned that the amount due by the publishers was about £465. On the Addendum, however, they had spent from £300 to £400 and that, of course, would come out of the balance at the credit of the committee. The committee, however, would be recouped, and more than recouped, by the sale of the Addendum itself.

Dr. MCVAIL, seconding the motion, spoke of the value and importance of the proposed small museum.

The Council adopted the report.

Inspection of Final Examinations.

The REGISTRAR (Mr. H. E. ALLEN) read a report which stated that

> The Executive Committee think it well to report to the General Council what steps they have taken consequent to the resolution passed by the General Council on May 30th, desiring them to forthwith make arrangements for a systematic inspection and visitation of the final examinations of the several licensing bodies. Time has not yet allowed for the completion of these arrangements, but the Executive Committee have decided that, following the precedent adopted in 1892, it will be well to spread the inspection over three years, and to inspect the examinations in the following order:—First year: Scottish Corporations, Irish Universities. Second year: Irish Corporations, English Universities. Third year: English Corporations, Scottish Universities. From information already obtained by the office a calendar will be prepared showing the dates when these respective examinations take place in each year, and members of Council will be requested to state at the close of each year the examinations which they would be prepared to visit along with the inspector, it being understood that it is not the custom for a member to visit the examinations of those bodies with which he is officially connected or in his own division of the kingdom.
>
> The committee agreed to invite Sir George Duffey to undertake the duties of inspector for the year 1901.

Dr. MACALISTER moved that this report be received and entered on the minutes. He said that it should be put on the minutes as a record and that it did not require the adoption by the Council.

Mr. BRYANT seconded the motion.

Dr. GLOVER supported the committee's recommendation.

The motion was agreed to.

The PRESIDENT asked that the names of members who would act as visitors should be sent to him before the end of the session, it being understood that, following precedent, there should be different visitors for the corporate bodies and for the universities.

Irish Arrangements.

The REGISTRAR read the following communication from the Royal College of Surgeons in Ireland as to the severance of its connexion with the Apothecaries' Hall, Dublin:—

> Royal College of Surgeons in Ireland, Dublin,
> July 20th, 1900.
>
> SIR,—I am directed by the President and Council to inform you all connexion between this College and the Apothecaries' Hall for the holding of Conjoint Examinations ceased on the 1st of the present month.
>
> Yours truly,
> JOHN BARTON, F.R.C.S., Secretary of Council.
>
> H. E. Allen, Esq., Registrar.

Dr. MACALISTER, who moved that this communication should be entered on the minutes, mentioned that candidates for the "final" could go to the Apothecaries' Hall.

The communication was received and entered on the minutes.

Bogus American Diplomas.

The next business on the programme was the receipt of a communication remitted to the General Medical Council by the Executive Committee from the Foreign Office in regard to the sale of false American diplomas

Foreign Office, Sept 24th 1900

SIR,—I am directed by the Secretary of State for Foreign Affairs to transmit to you, for the information of the General Council of Medical Education, the accompanying copy of despatches from Her Majesty's Consul at Chicago respecting the sale of false American diplomas

I am, Sir, your most obedient humble servant

F. H VILLIERS

The Registrar of the General Medical Council

[COPY]

British Consulate, Chicago, July 3rd, 1900

MY LORD,—I beg to report for your lordship's information that the postal inspector of Chicago has at last been able to arrest and to have held in heavy bail for trial Dr. Armstrong and his associates of the People's Institute, Van Buren street, Chicago

Armstrong and his partners under various names have been doing a very lucrative business in selling diplomas to persons in England, and their agent, Z Whightman Van Appin, disposed of large numbers of useless diplomas in British India I hope to obtain a list of the persons who purchased these diplomas in India from Mr Van Appin and will at once forward it to your lordship

From a postcard that has been held by the postal authorities, who have been so good as to communicate it to me, I see that Mr Allan Fisher, who styles himself M.D and Ph D, writing on the 5th ult. from ' Mere " 'Wiltshire,' to Dr Armstrong, People's Institute, Van Buren street, Chicago, states that he has delivered a diploma of D D to a Mr Johnson (no address given), who is very much pleased with it, and that he had hopes of selling two M D diplomas for the sale of which he was in treaty with persons whose names are not mentioned

The postal authorities also hold return postcards showing that Dr. Armstrong and company are in treaty with the following parties either to sell diplomas or have already sold them diplomas:—

1 Rai Tharoda Kanto Lahiri, M D, 6612, Simla street, Calcutta, and is corresponding with:—

2. Dr Hassall, 76 and 80 Paul street, Manchester, England,

3 J M Lethera, M D, House No 3, Zier Thost Bang (?), Girgaum, Bombay, India.

This address is very indistinctly written

4 Z Wightman Van Appin, c/o Dr J. Murdoch, 714, Shelby street, Louisville, Kentucky.

I think the police will probably be able to find out some useful details of the business of bogus diploma selling by Dr Armstrong in Great Britain from Mr Allan Fisher, who is now acting as selling agent for the diplomas of the Independent Medical College and the Metropolitan Medical College of Chicago, Illinois These so-called colleges have charters issued by the State of Illinois, the laws of the State being very lax in the matter of granting such charters, but their diplomas are being sold all over Great Britain and British India, and probably in the colonies to anyone who may be willing to buy them

It is possible that Mr Allan Fisher has been duped by Armstrong and company, but he is now evidently acting as their agent and sells D D Diplomas as well as M D, signed by the same people, or rather by the same person, as it has been found out that all the signatures are made by a girl in different handwritings

Armstrong and his associates have been held in heavy bail for trial for making use of the mails to defraud, and for the moment the diploma mill is said to be closed

Her Majesty's Government of India may also be able to find out through the addresses I have given above if there has been anyone appointed in India to sell the diplomas

Mr Z Wightman Van Appin himself bought a Ph D and M D diploma for $144, and then was sent to India with a quantity of blank diplomas of all kinds to fill in

I will inform your lordship later on of the result of the trial of Armstrong and company.

I have, &c,

(Signed) WM WYNDHAM,

Her Majesty's Consul

Her Majesty's Principal Secretary
of State for Foreign Affairs

[COPY]

British Consulate, Chicago,
August 31st, 1900

MY LORD,—With reference to my dispatch, No 25 of the 3rd July last, I have now the honour to forward a list of persons who are residents in Great Britain India and the colonies who appear to have been duped by the diploma mill of Armstrong and company, of Chicago:— Pectells Wm E, Melbourne Australia, Fisher, M D, Allan, Bristol England, Thomson D D S, Benj Sydney, Australia, Chand M D, Tatch, Ludhiana, India, Kennedy, M D, E M, Bristol, England Secretary, Bank of Bengal, India, Lear, W E, Brighton, Canada, Allahabad Bank, Allahabad, India, Fisher, A Leigh, England, Newton, Ph D, F H, Melbourne, Australia, Hoverban, M D, N Desar, Baroda, India, Nanaratly, M D, B H, Ahmedabad, India, Sarvana D F, Bombay, India, Kapen M D, R. D, Baroda, India, Trilli, Podley Mort, Jamaica, W I

There are doubtless many others who have purchased bogus diplomas, but I have as yet only found out the above cases

I have, &c,

(Signed) WM WYNDHAM,

Her Majesty's Consul

The Secretary of State,
Foreign Office.

The REGISTRAR explained that none of the names in the foregoing list were those of practitioners registered in the British Medical Register

Dr MACALISTER said it was desired that the utmost publicity should be given to these documents That, he assumed, would be obtained by the Council's placing the documents on their minutes

It was resolved to receive the communications and enter them on the minutes

Dr. GLOVER thereupon moved:—

> That the President be requested to thank the Secretary of State for Foreign Affairs for transmitting to the Medical Council the foregoing communication regarding the sale at Chicago of false American diplomas, and to ask that the Council may be informed as to the result of the proceedings against Dr Armstrong and his associates

He thought that it would be well if the trade in bogus degrees could be stopped, and he thought that the steps taken by the Chicago authorities and our consul in that city would meet with the approval of the medical profession of the United States In placing the documents in question on the minutes of the Council and passing his motion he felt that they were only advancing the views of the educationists of America who were taking great interest in this question.

Dr LOMBE ATTHILL seconded the motion, which was unanimously agreed to

Exemption from Examination

The Council next considered a report by the Registrar on evidence of previous examination required by the various licensing bodies from candidates claiming exemption from further examination in certain subjects This report was —

I On May 30th 1900, the General Council passed the following resolution "That the Registrar be instructed to inquire of the various examining boards what evidence they require to be produced by candidates who claim to be exempted from examination in particular subjects on the ground that they have already passed in these subjects before other licensing bodies" II Pursuant to this instruction the Registrar on June 11th, 1900 addressed a circular letter of inquiry to all the licensing bodies, to which all have replied III An abstract of the answers received is set forth in what follows —

The Royal College of Physicians of London —With regard to the First Examination.—When a candidate claiming exemption from any or all of the parts of this examination can show that he has passed in any or all of them at an examination for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, or when a candidate can show that he has obtained a colonial, Indian, or foreign qualification (not necessarily a degree in medicine) entitling him to practise in the country in which it has been conferred, he must produce a certificate from the president, dean, or secretary of the university stating definitely the subject or subjects in which he has passed In some cases proof of the possession of the qualification is accepted as evidence, provided there is further evidence as to the curriculum including examination in the subjects of the first examination *With regard to both the first and second examinations* — Any student of a university of the United Kingdom who can prove by a certificate from the dean, registrar, or other recognised official of the university that he has passed in the subjects of these examinations of the College at an examination for a degree in medicine can claim exemption from such examinations The possession of a degree in medicine or surgery of a colonial, Indian, or foreign university recognised for the purpose exempts the holder from both these examinations Certificates of the course of study must be produced, but evidence of the possession of the degree is accepted as proof of the passing of equivalent examinations

The Royal College of Surgeons of England.—Refers the Council to the answer sent by the Conjoint Board

The Conjoint Board of the Royal Colleges of Physicians and Surgeons of England —Candidates desiring exemption from the subjects of the first and second examinations are required to produce a certificate from the dean, secretary, or other authority of the university stating the subjects in which they have passed in the examination for a degree in medicine of the university In certain cases, however, especially in the cases of graduates in medicine of recognised universities with the requirements and subjects of the various examinations of which the Board is acquainted, the degree itself is accepted as evidence that the earlier examinations have been passed

The Apothecaries' Society of London —Candidates presenting themselves for the final examination of the Society and who have passed the primary examination of some other recognised body are required to produce direct evidence from the secretary of such body as to the subjects passed, with a clear statement that the said subjects are complete and not elementary No exemptions from the final examination are made.

The University of Oxford.—Allows no exemptions.

The University of Cambridge —Allows no exemptions

The University of Durham —A candidate who has passed the first examination of the English Conjoint Board is exempt from the subject of biology in the first examination of the University. A certificate from the secretary of the board is required Candidates holding a qualification from a recognised licensing board of the United Kingdom at the date of entry for the first examination of the University are exempt from examination in elementary anatomy and biology, but are required to pass in chemistry and physics The presence of the candidates' names on the Medical Register is the evidence accepted in this case.

The University of London —Allows no exemptions

The Victoria University —Exemptions seldom allowed. Qualified practitioners only are exempted from particular subjects of the examinations for the M B degree and the Medical Register is accepted as evidence, though certificates could be required if it were desired to know what particular examination a candidate had passed.

Royal College of Physicians of Edinburgh —The Single Licence only is granted to candidates who hold a recognised qualification in surgery on their filling up a prescribed declaration and producing their diploma

Royal College of Surgeons of Edinburgh.—The Single Licence only is granted to candidates who hold a recognised qualification in medicine on their lodging a schedule of curricula and producing their diplomas.

Faculty of Physicians and Surgeons of Glasgow.—Exemption from any particular subject can only be obtained on the production of an open certificate or the receipt of a private official attestation proving that a candidate has already passed in that subject before another licensing body.

Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow.—Candidates for exemption in any subject of any examination must produce a certificate—or cause an official communication to be sent direct to the board—showing that they have passed an equivalent and final examination in that particular subject before one of certain specified boards.

University of Edinburgh.—The only exemption from examination granted to candidates for the degrees of M.B. and Ch.B. is in the case of those who have completed a course of study and passed an examination in botany, zoology, physics, or chemistry at a university of the United Kingdom or at any other university whose course of study and standard is considered by the Senatus Academicus to be satisfactory; and they must, in the case of a university of the United Kingdom, produce a certificate signed by the dean of the university in question stating the subjects passed in, and that they qualify for a degree in arts or science; and in the case of other universities a similar certificate must be produced, together with the diploma, or simply the diploma and a reference to the calendar setting forth the regulations under which it was obtained.

University of Glasgow.—Examinations of other licensing bodies are not recognised as exempting from medical professional examination, but candidates claiming exemption from certain scientific subjects on the ground of having already completed a course of study qualifying for a degree in science or in arts, passed in such subjects at a university of the United Kingdom or other university specially recognised for the purpose by the university court, must produce university certificates showing that they have passed the examination in the particular subject or subjects in which exemption is claimed.

University of Aberdeen.—Same as the University of Glasgow.

University of St. Andrews.—Same as the University of Glasgow.

Conjoint Board of the Royal Colleges of Physicians and Surgeons of Ireland.—It is the invariable practice that a formal certificate must be produced, signed by the proper officer of a licensing body, at which any subject has been passed exemption from which is sought.

Royal College of Physicians of Ireland.—The Single License granted only to registered medical practitioners, who must produce their registration certificates. As to examinations conducted conjointly, the requirements are those stated by the Conjoint Board in Ireland.

Royal College of Surgeons in Ireland.—Same as the Conjoint Board in Ireland.

Apothecaries' Hall, Dublin.—A certificate must be produced, or a letter directly forwarded by the registrar of the licensing body at which the candidate states that he has passed certain subjects and is entitled to exemption in respect of them.

University of Dublin.—A certificate must be produced, signed by the accredited official of a licensing body, showing that an examination has been passed in a particular subject, or a diploma is held to cover all the examinations required to be passed in order to obtain it.

Royal University of Ireland.—Allows no exemptions.

Mr. Horsley, who thought this report exhibited a dreadful state of affairs in regard to the medical education in this country, moved—

> That a schedule of the universities or licensing bodies recognised for the purposes of exemption from examination be obtained from each licensing body.

He said that in justice to their students the subject was one which ought to be fully inquired into by the Medical Council. It was not good enough to say that "the degree itself was accepted as evidence that the earlier examinations had been passed." The Germans took that view and if that was not good enough for the Germans that should not be good enough for them.

Sir William Thomson seconded.

On a division 12 voted for and 12 against. The President gave his casting vote against, in order, as he said, to observe the universally followed rule in such cases—namely, "keep things as they are."

Mr. Horsley's proposal was accordingly rejected and the report was received and entered on the minutes.

Dental Business.

Dr. MacAlister submitted the following report from the Executive Committee on Dental Business transacted by it since the May session, viz.:—

> (*a*) The prescribed conditions in each case having been duly fulfilled the names of the under-mentioned persons have been restored to the Dentists' Register, from which they had been erased in conformity with the provisions of Section 12 of the Dentists' Act:—Isaac Bailey, Ernest S. Barlow, Emile H. Chapman, Hedley H. Ham, Frank A. Harsant, Frederic E. Ladmore, Joseph Moyle, Frederick G. Roberts, James Stett, Ernest R. Tebbitt.
>
> (*b*) The committee considered and approved a Standing Order to be substituted for the present Standing Order XV., 11.

(*c*) The committee further considered the cases of Mr. E. H. C. Bailey and Mr. F. W. Bailey, with regard to whom, on May 29th, they had passed the following resolution:—

> That Mr. E. H. C. Bailey and Mr. F. W. Bailey be asked to produce the certificates required by the regulations under which they commenced their studies in proof of their having fulfilled the requirements of the Board.

Whereupon it was resolved—

> That the further consideration of these cases be postponed till the return of Mr. Bailey from Australia.

Nothing further having been heard from Mr. Bailey in regard to this matter the committee resolved—

> That the cases of E. H. C. Bailey and F. W. Bailey be referred to the Dental Committee for inquiry into the facts.

This report, on the motion of Dr. MacAlister, seconded by Mr. Tomes, was received and entered on the minutes.

The Council adjourned.

Wednesday, Nov. 28th.

The Council met again to-day, Sir William Turner being in the chair.

The Diploma in Public Health.

The first business on the programme was to receive the following report by the Public Health Committee, viz.:—

1. Instructions to the Committee.

On Dec. 5th, 1899, the General Medical Council passed the following resolution in regard to a report by the Committee on the interpretation given at different places to the regulations of the Council as regards the course of study for the Diploma in Public Health:—

"That the report of the Public Health Committee as amended be received and entered in the minutes and that copies be sent to members of the Council and transmitted to the bodies which confer diplomas in public health for their observations on the recommendations made by the Committee."

2. Analysis of the Remarks of the Bodies.

The Committee now present the following analysis of the remarks of the bodies on the report of the Public Health Committee.

1. The Committee report that five bodies state that they have practically no criticisms to offer—viz.: (1) the University of Oxford; (2) the University of Durham, (3) the University of London; (4) the University of Aberdeen; (5) the University of Dublin; while one body "has the matter still under consideration."

2. Other licensing bodies present observations in regard to the several recommendations of the Committee.

3. As regards Rule I. (1), viz.: "(1) A period of not less than 12 months shall elapse between the attainment of a registrable qualification in medicine, surgery, and midwifery, and the admission of the candidate to any examination, or any part thereof, for a diploma in sanitary science, public health, or state medicine," the Committee in Recommendation I. advised that this rule be maintained. The licensing bodies are practically unanimous in favour of the recommendation.

4. As regards Rule I. (2), viz.: "(2) Every candidate shall have produced evidence of having, after obtaining a registrable qualification, attended during six months practical instruction in a laboratory or laboratories, British or foreign, approved by the body granting the diploma, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught," the Committee made the following Recommendation II.—viz.: That Rule I. (2) be so far modified as not necessarily to require evidence as to attendance on a course of practical laboratory instruction in the case of candidates already competent in the branches of study in question; and that it read as follows:—"(2) Every candidate shall, after obtaining a registrable qualification, either have produced evidence that he has attended a sufficient course of practical instruction in a laboratory or laboratories, British or foreign, approved by the body granting the diploma, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught; or shall otherwise have produced evidence that he has received adequate instruction in the branches of study referred to."

The Licensing Bodies have made the following observations in regard to this recommendation:—

(i.) The Committee of Management of the Two Royal Colleges of Physicians and Surgeons of England

feel that the sentence in this proposed Rule "adequate instruction in the branches of study referred to" is "too indefinite, and they consider that it is desirable for every candidate to attend a recognised course of instruction, although the number of attendances may well be left open as proposed in the first part of the clause. The committee therefore suggest the omission of the sentence after the word 'taught.'"

(ii.) The University of Cambridge.

"The committee of the State Medicine Syndicate of the University of Cambridge, which has conducted examinations in sanitary science for medical officers of health since 1875, have considered the report of the Public Health Committee of the General Medical Council, dated Dec. 4th, 1899, and beg leave to submit to the Council the following observations:—

"No serious difficulty has been found in the working of the Council's rules in their present form.

"The present requirement in general terms of two courses of six months each (not necessarily non concurrent throughout their whole extent) in laboratory work and in out-door sanitary practice is satisfactory, and should not be appreciably relaxed. It is to be feared that such a general relaxation of the rule regarding these courses as appears to be proposed in the report would tend to depreciate the standard of that special and systematic study of the several branches of science that concern public health which is now required of candidates for the diploma. The requirement of six months' practical sanitary work (of all pertinent kinds) should be retained by all examining bodies; and the practical courses of laboratory instruction should be limited to such as are recognised and approved by these bodies. The study of chemistry, physics, and general pathology (including the elements of bacteriology), which usually forms part of the curriculum for an ordinary medical qualification, is not sufficiently relevant to the special duties of a medical officer of health to take the place of the study of their specific applications to hygiene which the present rules enjoin.

"The renouncement of the present requirement of these post-graduate courses would therefore have a deteriorating effect, and would tend to increase the proportion of rejected candidates at the examinations "

(iii) The Victoria University

suggests the following reading of the proposed recommendation: "Every candidate, *before admission to the examination*, must either produce evidence that he has attended *satisfactorily* a sufficient course of practical instruction in a laboratory or laboratories, British or foreign, approved by the body granting the diploma, in which chemistry *as applied to public health*, bacteriology *as applied to public health*, and the pathology of the diseases of animals transmissible to man, are taught; or shall otherwise have provided evidence that he has received adequate instruction in the branches of study referred to " (The suggested changes are italicised)"

(iv) The Committee of Management of the Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow

"The committee cannot help viewing the adoption of the proposed alteration with considerable doubt and apprehension '

(v) The University of Edinburgh.

takes exception to the view that laboratory work done before qualification can be accepted as an equivalent for the six months of special laboratory work required under the existing rules of the Council

"While examination is the only means of testing a candidate s knowledge, it is regarded by most examiners as an imperfect one Under the present regulation there is the added guarantee that the candidate has given six months to the special work at a time when he can devote himself entirely to it and related studies "

(vi) The University of Glasgow

"is unable to agree with the modifications of Rule I (2) as proposed," and suggests as an alternative to the six months required by the existing rule the following: "or (*b*) shall have produced evidence by the course of study for a degree in science which he has obtained, that he has received adequate instruction in the branches referred to,'

(vii) The Royal College of Surgeons in Ireland

"The suggested modifications contained in the proposed new rules 2 and 3 seem to this Council to reduce the certificate to the level of mere shams "

5. As regards Rule 1 (3), viz —

"(3) *Every candidate shall have produced evidence that during a* period of six months after obtaining a registrable qualification he has practically studied the duties of out-door sanitary work—

' (*a*) In England and Wales either under the medical officer of health of a county or of a single sanitary district having at the date of the last census a population of not less than 50 000 or the medical officer of health of a combination of two or more sanitary districts having collectively at the date of the last census a population of not less than 35 000, or

"(*b*) In Scotland or Ireland under the medical officer of health of a county or of one or more sanitary districts having at the date of the last census a population of not less than 30,000; or

"(*c*) Under a medical officer of health who is a teacher in the department of public health of a recognised medical school

"The certificate of an assistant officer of health of a county or a large urban district may be accepted, provided the medical officer of health of the county or district consents to the assistant officer giving such instruction

"*** Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation "

The Committee made the following Recommendation 3, viz —

That the first paragraph of Rule I (3) be modified so as to read as follows:—

"Every candidate shall have produced evidence that, after obtaining a registrable qualification, he has practically studied the duties of outdoor sanitary work under a medical officer of health '

The licensing bodies have made the following observations in regard to this recommendation —

(i) The Royal Colleges of Physicians and Surgeons of England

make no comment

(ii) The Victoria University

suggests the following modification "Candidates to produce certificates 'of having received instruction in practical sanitary work on not less than 60 days under the medical officer of health of a county or of a large urban district.'"

(iii) The Conjoint Board of Scotland

say that the proposed changes generally "appear to them to be retrograde in character "

(iv) The University of Edinburgh

"thinks that three months is a reasonable minimum period for this instruction

(v) The University of Glasgow

The Committee of Faculty cannot acquiesce in the modification of Rule I (3) proposed by the Committee of Council and it recommends that for the rule as proposed the following should be substituted —

"Every candidate shall have produced evidence that, after obtaining a registrable qualification he has practically studied for a period of not less than three months the duties of a medical officer of health, provided always that this course is not taken concurrent with the course of laboratory instruction, or for a period of not less than six months where this course and that of laboratory instruction are allowed to run concurrently

The committee sees grave objections to the rule as proposed In the first place, no period of time during which the course of practical study must run is laid down, and no definite conception is given of the kind or character of practical study in which the candidate is to engage indeed, a simple certificate by a qualified medical officer of health would meet the demands of the proposed rule, and, in any case serious differences of interpretation to the term "practically studied" would certainly result, depending upon the individual conceptions thereof of different medical officers of health Already the practice in this respect is sufficiently divergent to demand the laying down of a minimum fixed period or even programme of study Obviously, since the objective point of most candidates for Diplomas in Public Health is the position of medical officer of health it becomes of the first importance that candidates should be well prepared, not only for the examinations precedent to the obtaining of a diploma, but more especially for the efficient practical performance of the duties of such an office. It may be urged that an efficient board of examiners is an effective safeguard against the imperfectly prepared candidate To some extent this is true, at the same time, it is by no means impossible for a candidate imperfectly equipped in practical knowledge but well prepared in book knowledge, to pass the necessary examination in this department, and if the Diploma in Public Health is to maintain its high character and to form evidence of the fitness of its possessor for the important practical duties of a medical officer of health, it is essential that the evidence of instruction in practical sanitary work ought to be substantial In short, unless a definite minimum period of carefully defined study in this department is laid down in the rule, there would be no guarantee as to its efficiency

On the merits of the question the Committee of Faculty believes that a period of three months would be sufficient for the study of practical sanitation provided that the whole time of the candidate be devoted to the subject, and that the period of study did not run concurrently with the course of laboratory instruction, or, alternatively, a period of six months running concurrently with the other But the Committee of Faculty is of opinion that the length of time devoted to the study of practical sanitation does not so much matter as the kind and range of the subjects studied, and in order to ensure some general uniformity of range of instruction it would suggest that a schedule of subjects to be studied should be drawn up by each medical officer of health who is entitled to teach candidates, and should be submitted to each body granting a diploma in public health for approval, in conformity with which certificates of instruction should be drawn. Such a method would tend to prevent inequalities of practice in the granting of such certificates

The committee is in entire concurrence with the views of the Committee of Council regarding the necessity of engaging the services of competent examiners for each subject of examination by the bodies granting diplomas, and it also agrees with the proposed addition (*d*) to Rule I (3)

(vi) The Royal College of Physicians of Ireland

recommend that Rule I (3) be modified so as to read as follows —

"Every candidate shall have produced evidence that after obtaining a registrable qualification he has practically studied the duties of *outdoor sanitary work under a medical officer of health in England or* Scotland, and in Ireland under such persons as may be approved by the licensing bodies "

(6) As to recommendation 4 viz.:—

In view of the increased latitude thus advocated as regards the teaching to be required under Rule I (2) and (3), your Committee have arrived at the further conclusion that the bodies granting diplomas in public health should always engage the services of (*a*) Examiners competent in the sciences of bacteriology, chemistry, &c, in relation to public health, and (*b*) examiners who have themselves had practical experience in the outdoor work of a medical officer of health

The Committee report that Recommendation 4 is practically accepted by all the bodies

(7) As to Recommendation 5, viz. —

It having come to the knowledge of the Committee that there would be advantage in making some extension in the number of the medical officers of health entitled to certify as to compliance with the terms of Rule I (3) your Committee are of opinion that there would be advantage in adding to the officers defined under (*a*), (*b*) and (*c*) the following —

"(*d*) Under a medical officer of health who devotes his whole time to public health and allied duties and is not engaged in private practice '

The licensing bodies have made the following observations in regard to this recommendation,—

(i) The University of Cambridge

reports that as to the question of the overlapping of the prescribing courses of laboratory work and *outdoor sanitary practice there seems* to be no good reason for laying down a rule of the Council No harm *can arise from* a certain latitude to candidates in the distribution of their time, provided that the courses are efficient and not hurried through in a few weeks, and that the examinations are of a sufficiently searching character

The Committee accordingly deem it inexpedient for the purposes of the diploma of the University as well as of other examining bodies that the Council s rules should be relaxed to the extent contemplated in the report.

The Committee approve of the proposed extention of Rule I (3) *d* as to work with a medical officer of health who devotes his whole time to public health and allied duties, and is not engaged in private practice

(ii) The University of Edinburgh

are of opinion —

(*a*) ' That the smaller sanitary areas do not provide sufficient opportunities of study to ensure the requisite amount of practical training " and

(*b*) "That if the pupil possessed a competent knowledge of the scientific principles which form the subject of hygiene the amount of this tuition might be reduced, '

(c) ' That three months is a reasonable period for this instruction "

3 Conclusions.

Your Committee have duly studied the observations and representations of the several licensing bodies which have commented on the provisional recommendations of 1899 Further and with particular reference to demand for practical instruction in the duties, routine and special of medical officers of health, the Committee have ascertained, from official sources of information, that in England and Wales and in Scotland facilities already exist, and in Ireland are likely to be ere long forthcoming sufficient to meet in this sense the wants of candidates for the Public Health Diploma.

Again your Committee have considered the case of candidates who hold official positions under the Secretaries of State for War for India, and the colonies, *so fully referred to in the report of the Public Health* Committee, December 1899 —(*Minutes*, xxxvi, p. 755.)

With these additional data before them, and upon reconsideration of the whole subject, your Committee recommend the following rules in substitution for those now in force:—

Draft Rules for Diploma in Public Health.

I. A period of not less than 12 months shall elapse between attainment of a registrable qualification in medicine, surgery, and midwifery, and the admission of the candidate to any examination, or any part thereof, for a diploma in sanitary science, public health, or State medicine.

II Candidates shall be separated into two classes, juniors and seniors.

Juniors to be candidates in regard of whom 10 years have not elapsed since attainment of their registrable qualification.

Seniors to be candidates who have possessed a registrable qualification for 10 years.

III. Junior candidates.

(1) Every candidate shall have produced evidence of having, after obtaining a registrable qualification, attended during six months practical instruction in a laboratory or laboratories, British or foreign, approved by the body granting the diploma, in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught.

(2) Every candidate shall have produced evidence that after obtaining a registrable qualification he has during six months, other and separate from the like period employed in laboratory work as required under (1), been associated day by day in the duty, routine and special, of public health administration such as is exercised:—

(a) In England and Wales by the medical officer of health of a county or of a single sanitary district having a population of 50,000, or by a medical officer of health giving his whole time to public health work.

(b) In Scotland by a medical officer of health of a county or counties, or of one or more sanitary districts having at the date of the last census a population of 30,000

(c) In Ireland by a medical superintendent officer of health of a district or districts having at the date a population of 30,000; or

(d) By a medical officer of health who is also a teacher in the department of public health of a recognised medical school.

(e) The certificate of an assistant medical officer of health of a county or of a sanitary district of 50,000 population may be accepted, provided the medical officer of health of the county or district permits the assistant officer to give such instruction.

(3) Every candidate shall produce evidence that, after obtaining a registrable qualification, he has, during three months, practically observed and studied the clinical and administrative work pertaining to the medical superintendence of a hospital for infectious diseases

The three months devoted to study in this sense may be concurrent with the administrative work referred to under Section (2), but not with the laboratory work of Section (1).

IV. Senior candidates

(1) Every candidate shall have produced evidence of having, after having obtained a registrable qualification, attended during six months practical instruction in a laboratory or laboratories, British or foreign, approved by the body granting the diploma in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught

(2) Every candidate shall have produced evidence:

(a) That he has himself held during five years an appointment as medical officer of health in a district with a population of 5000; or

(b) That he has, during not less than 60 days, received instruction in practical sanitary work under a medical officer of health in the United Kingdom administering a district having a population of 20,000 and upwards

The 60 days thus devoted to practical sanitary administrative work may be concurrent with the laboratory work required of seniors under Section (1).

Mr. TEALE, chairman of the Committee, moved that the report be received and entered on the minutes. In doing so he explained the position of the Council with regard to the Diploma in Public Health and the circumstances which had led to the inquiry by his committee. It was in May, 1898, he said, that Sir William Gairdner called attention to apparent diversities of interpretation given at different places to the regulations of the Council as regards the course of study for this diploma. The principal requirement involved was that as to the candidate having practically studied the duties of outdoor sanitary work under a medical officer of health during a period of six months. In the report now presented there was dealt with the case of candidates who held official positions under the Secretaries of State for War, for India, and for the Colonies. The committee had considered whether anything could be done to meet the case of these candidates without reducing either the education or the value of this diploma, and they had come to the conclusion that something might be done by dividing the candidates into two classes, one class to consist of men who went in for the diploma soon after their ordinary qualification and the other to consist of men who went in for it 10 or more years after their ordinary qualification. The one class they proposed to call juniors and the other seniors. It would be said that they were letting down the diploma, but in his opinion they were not doing so. There surely was a great difference between men of 10 years' experience and practice in official appointments and men only commencing work. The former would get more out of nine months than the latter would get out of twelve months He and some of his colleagues on the Committee felt that it was a question whether it was desirable by the action of this Council to restrict too much the sanitary office to men who at once became specialists in the matter—to divorce from it too much men who had been in general practice and who had acquired thereby experience and breadth of view.

Dr. BRUCE seconded the motion.

Sir JOHN BATTY TUKE moved as an amendment that the report be re-committed, and he said he did so as a member of the Council who had perhaps had more to do with the forming of the regulations for this diploma than anyone now present. Eleven years ago he acted with Sir John Simon and Sir John Struthers, and the general results of their advice had been accepted by the Council. He opposed the report on the ground that it lowered the general tone of education and of examination. He could not help regretting that the report had not been sooner in the hands of members in order that they might have examined it carefully and compared it with the other literature on the subject. The Acts of Parliament conferred on the Council very peculiar and exceptional powers over these Public Health diplomas—powers materially different from those they exercised over professional education examination and registration, and the Council had endeavoured to set a high standard of proficiency—in fact, to put the examinations upon the honours level. He would like to know who had asked for any charge in the rules of the Council. They were told that the pressure came from departments of the Government, who requested that in order to allow officers abroad to obtain these diplomas, they should reduce the qualifications. He saw no reason for this. If the Government wished to bring what they desired about the simple thing for them to do was to grant their officers study leave. One of the great grievances of medical men in the army service was that this study leave was not granted them, and if the Council agreed to the change now proposed it would only make the War Office the more persistent in its refusal. The licensing bodies had not asked for the change; on the contrary, they opposed it, and it was a new feature in the deliberations of this Council to find the bodies asking for the maintenance of a high order of education and this Council endeavouring to lower it. In conclusion, he submitted that no sufficient reason had been given for the proposed change. Certainly there was no dearth of diplomates in Public Health, for if they looked at last year's Register they would find that 150 men had been granted this diploma, which was something like five times more than the necessities of Great Britain and Ireland.

Dr. GLOVER seconded the amendment.

Sir CHRISTOPHER NIXON, after complaining of having had insufficient time to study the report, said that he hoped that any conclusion the Council came to on this subject of the Public Health diploma regulations would be final. Although he thought the report capable of amendment, he was not prepared to adopt the extreme step proposed by Sir John Batty Tuke of sending it back to the committee.

Dr. MCVAIL said that he thought the Council should proceed to the consideration of the report. He would remind the Council that the late Sir Richard Thorne had told them that he saw great necessity for making some provision for men who had been a long time in the profession getting their diploma upon a somewhat shorter curriculum, and he would point out that while the committee proposed that the curriculum for these men should be somewhat different they did not propose a different examination. He submitted that a man who had been in practice for a number of years did not need so long a period of study as a man who had only finished his student career. A study of the proposed draft rules would show that there was no lowering of the standard but rather a raising of it.

Sir WILLIAM GAIRDNER recalled the circumstances which led to the inquiry by the committee and said that the work of the committee had gone somewhat beyond what was originally contemplated. He must support the amendment because it appeared to him that the Committee left the question in a most unsatisfactory position

Dr. BRUCE repudiated the imputation that there was any reducing of the present restrictions. They were not reducing the restrictions and, indeed, if they struck a balance they would find that they were increasing them.

Dr GLOVER said that he felt that the constant recurrence of this important subject was most unsatisfactory and he saw no justification for its resuscitation on the present occasion He regarded recent events in our colonies as a striking object lesson in the sanitary methods that prevailed there and he thought it would be a most unfortunate thing if in the face of this object lesson they reduced their requirements in the case of colonial candidates It was an entirely new departure for this Council to divide candidates into two classes. It might be good for the colonial candidates, but it could not be good for the colonies themselves. Another point to be remembered was that with the present standard there was an ample supply of candidates

Mr. Brown hoped that the report would not be sent back to the committee in this unceremonious manner, but would be discussed by the Council.

Dr. MacAlister said that he should like to support the amendment because the report did not sufficiently explain the reasons at the back of this pressure from the Government departments and because no provision was made for limiting the proposed relaxation to the officers of these departments.

On a division being taken the amendment of Sir John Batty Tuke was rejected by a large majority. The Council thereupon agreed to receive the report and to enter it on the minutes. The consideration of the report was then taken in committee of the whole Council.

Mr. Teale moved the adoption of the first draft rule recommended by the committee, explaining that it was the same as the existing rule on the subject.

The committee agreed to the rule.

Mr. Teale then moved the adoption of draft rule No. 2, proposing that candidates should be separated into two classes, juniors and seniors.

Dr. McVail seconded this motion. The reasons which had led the committee to divide the candidates into two classes were reasons, he said, which had been growing upon the committee ever since it took up this work.

The President: Cannot you give us a better name than juniors and seniors?

Dr. McVail said he was seconding the proposal of the committee and perhaps, therefore, it would be for somebody else to suggest something different; he did not see how he could. The evidence had been accumulating all through the inquiry that there were many men in practice in the colonies and India in public appointments whom it was most desirable to induce to take the diploma in Public Health. What the Government departments had pressed the committee to do was to shorten somewhat the period of residence necessary in this country for obtaining the diploma and the committee thought that in the case of men of 10 years' experience the period might be shortened. Let the Council, however, clearly understand that there was no interference proposed with the standard of examination.

Dr. Atthill suggested that the classes might be described as A and B.

The President said that it was a question of professional standing, and surely some means could be devised of expressing that. He thought the words "juniors" and "seniors" most objectionable.

Mr. Horsley threw out the suggestion that the whole paragraph was unnecessary, because the men with the 10 years' experience could be dealt with by a proviso in the subsequent rules.

Mr. Teale said that he was quite willing to adopt this suggestion, though he thought the paragraph in the report had done good in the way of calling attention to the matter.

Sir John Batty Tuke said that, in his opinion, the subject was much too important to be disposed of in this fashion. Clearly it was proposed to do away with a measure of education which after all was of much more consequence than examination.

Dr. MacAlister suggested the use of these words "that a difference be made between the courses of study required of (*a*) practitioners under, and (*b*) practitioners over 10 years' standing."

Sir William Thomson submitted that the Council had no right to differentiate in this way between classes of candidates, and he for one would object to giving any gentleman who happened to have been in practice for 10 years a different curriculum from a gentleman who had come fresh from his ordinary medical qualification He had seen this principle in operation and he knew where it led

After there had been some further discussion, Mr. Teale asked leave to withdraw his motion in its entirety. Some exception was taken to the request and the President put from the chair the question that leave be given. This was carried and the motion consequently dropped.

Dr. McVail thought that the whole difficulty with regard to draft rule No. III. could be got over by the deletion of the word "junior."

The President: Then No. III. would be omitted altogether?

Dr. MacAlister said that if they passed the committee's recommendation they would make it very much harder for seniors.

Dr. McVail explained that if "junior" were omitted "senior" also would be omitted.

The proposal was then put and unanimously carried, the words "junior candidates" being struck out.

Mr. Teale thereupon moved that—

> "(1) Every candidate shall have produced evidence of having, after obtaining a registrable qualification, attended during six months' practical instruction in a laboratory or laboratories, British or foreign approved by the body granting the diploma, in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught."

Dr. McVail seconded.

Sir Christopher Nixon asked what was meant by instruction such as the committee proposed, especially in reference to "the pathology of diseases of animals transmissible to man."

Dr. Bruce was of the opinion that there could be no difficulty in such a matter, and if any difficulty was experienced that could be overcome by the exhibition of pathological specimens in the laboratory.

The motion was unanimously passed.

Mr. Teale next moved the adoption of Section (2) of recommendation III. The preamble of that, he explained, meant that it enforced six months' work.

Sir John Batty Tuke seconded.

Dr. MacAlister pointed out that if the Council adopted the rule as drafted they would be committing themselves to the principle of classification which had been suggested by the committee—namely, that there should be a distinction made between "junior" and "senior," or they would make it harder for seniors to pass examinations than hitherto.

On the suggestion of the President, the recommendation was altered so that it might read: "Candidates shall have produced evidence that after obtaining a registrable qualification," &c. After some conversation,

Mr. Brown said he thought that it would be very desirable to make a compromise on this matter. He suggested that three months of the course might run concurrently and the other three months not concurrently.

Mr. Power gave it as his opinion that there should be at least three months given up for practical sanitary work under the supervision of a medical officer.

Mr. Brown hoped that the Council would insist on securing in this section a period of six months—three months for work in the laboratory and three months' work non-concurrent.

Dr. McVail was not prepared to accept a cutting down of the curriculum to three months, which, he argued, the proposal before the Council really meant.

Dr. MacAlister and some other members denied the accuracy of Dr. McVail's interpretation, Sir John Batty Tuke remarking that in reality the committee's recommendation amounted practically to the addition of three months to, not their subtraction from, the curriculum.

The original proposal was withdrawn, and Mr. Teale, seconded by Sir John Batty Tuke, moved that the new rule, so far as the preamble was concerned, should read as follows:—

> "Candidates shall have produced evidence that after obtaining a registrable qualification, they have, during six months, of which at *least three months* shall be distinct and separate from the period devoted to laboratory work under regulation (1), been associated day by day in the duty, routine and special, of the public health administration under the supervision of," &c.

The recommendation, as thus modified, was agreed to, as also were the following modified subsections:—

> (*a*) In England and Wales the medical officer of health of a county or of a single sanitary district having a population of 60,000 or a medical officer of health giving his whole *time to public health work; (b) in* Scotland a medical officer of health of a county or counties or of one or more sanitary districts having a population of 30,000; (*c*) in Ireland a medical superintendent officer of health of a district or districts having a population of 30 000; or (*d*) by *a medical officer of health who is also* a teacher in the department of public health of a recognised medical school.
>
> *** The certificate of an assistant medical officer of health of a county or of a sanitary district of 50,000 population may be accepted provided the *medical officer of* health of the county or district permits the assistant officer to give such instruction.

Mr. Teale explained that subsection (*d*) was not to be regarded as referring to Ireland only. It was to be taken as a general provision applicable to England and Scotland and Ireland.

Sir Christopher Nixon moved that Ireland should be treated exceptionally and that it should have the option under subsection (*c*) of bringing in "such persons as may be approved by the licensing bodies." He, however, was supported by the vote of only five members of the Council and before the next matter was entered upon he jocularly informed the Council that all the Irish representatives had voted for his proposal.

Mr. Teale proposed the adoption of subsection 3, namely:—

> (3) Every candidate shall produce evidence that, after obtaining a registrable qualification, he has, during three months practically observed and studied the clinical and administrative work pertaining to the medical superintendence of a hospital for infectious diseases. The three months devoted to study in this sense may be concurrent with the administrative work referred to under section (2), but not with the laboratory work of section (1).

Dr. Bruce seconded.

Dr. McVail supported the motion, as it was in his view a great advance upon the present practice.

The President thought "administrative" was not needed at all.

Dr. Little, Dr. Lombe Atthill, and Sir Christopher Nixon agreed, while Sir William Thomson contended that, supposing the rule were passed, the words "and administrative" would prove unworkable.

Dr. MacAlister, seconded by Mr. Young, submitted a modification of the existing rule—namely:—

> That every candidate shall produce evidence that after obtaining a registrable qualification he has, during three months, attended the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration.

On a division Mr. Teale's motion was supported by only six members, whereas Dr. MacAlister's proposal received 17 votes, and was unanimously passed when it was put to the Council as a substantive motion.

Mr. Teale intimated that he would not trouble the Council with some remarks he had intended to make with reference to the classification suggested by the committee but rejected by the Council. Further he would entirely drop Section IV.

Dr. MacAlister said that he would bring up the report on the following day.

The Council resumed and adjourned.

Thursday, Nov. 29th.

The Council met again to-day and proceeded to the consideration of penal cases.

Medical News.

University of London.—At the M.B. examination held in October the following candidates were successful:—

First Division.—Samuel Herbert Lee Abbott, St. George's Hospital and Oxford; Donald Johnstone McGavin, Mason College and Queen's and General Hospitals, Birmingham; James Robert Morton, London Hospital; William Payne, Westminster Hospital; William Henry Willcox, B.Sc., St. Mary's Hospital; and Louisa Woodcock, London School of Medicine and Royal Free Hospital.

Second Division.—William Fielding Addey, University College; Robert Atwood Beaver, Liverpool Royal Infirmary; Guy Black, St. Thomas's Hospital; Sidney Herbert Bown, University College; Percy Frank Braithwaite, Owens College; Charles Hildred Brodribb, St. Mary's Hospital; Charles Henry Bullen, Mason University College; James Alfred Butler, Guy's Hospital; Alfred Henry Bygott, St. Mary's Hospital; Adrian Caddy, St. George's Hospital; Charles Holt Caldicott, Mason College; James Cameron, Royal Infirmary and University of Edinburgh and London Hospital; Wilfrid Henry Coltart, Mason College; John Bernard Davey, Middlesex Hospital; Frank Sherwill Dawe, B.Sc., St. Mary's Hospital; Alec Densham, Guy's Hospital; Margaret Bernard Dobson, Harriet Rosa Delo Ford, and Sarah Louise Fraser, London School of Medicine and Royal Free Hospital; Thomas Hall Gandy, St. Bartholomew's Hospital, Edward Alfred Gates, St Thomas's Hospital; Joseph Strickland Goodall, Middlesex Hospital; William Gough, B.Sc., Yorkshire College; Louisa Hamilton, Royal Free Hospital; Mary Hannah Frances Ivens, London School of Medicine and Royal Free Hospital; Lionel Capper Johnson, Owens College and University College, Liverpool; Alfred Ernest John Lister, St. Bartholomew's Hospital; John Wishart Little, St. Thomas's Hospital; Olive McDougall, London School of Medicine and Royal Free Hospital; William Halliburton McMullin, King's College; Patrick Thurburn Manson, Guy's Hospital; Edith Neild, School of Medicine for Women and Royal Infirmary, Edinburgh; Eugene Michael Niall, St. Bartholomew's Hospital; Cyril Alfred Rankin Nitch, St. Thomas's Hospital; William Paynter Noall, Owens College and Manchester Royal Infirmary; Mabel Paine, London School of Medicine and Royal Free Hospital; Thomas Massey Pearce, St. Bartholomew's Hospital; Mary Elizabeth Phillips, London School of Medicine and Royal Free Hospital; Miles Harris Phillips, University College and Royal Infirmary, Bristol; Thomas Copeland Savage, University College; Margaret Sophia Sharp and Amy Jane Guy Smith, London School of Medicine and Royal Free Hospital; William Smith, Bristol Medical School and St. Bartholomew's Hospital; Alfred Bertram Soltau, London Hospital; Hackworth Stuart, University College; Kathleen Olga Vaughan, London School of Medicine and Royal Free Hospital; Rupert Waterhouse, St. Bartholomew's Hospital; and Florence Elizabeth Willey, B.Sc., London School of Medicine and Royal Free Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

University of Cambridge.—At a congregation held on Nov. 22nd the following were admitted to medical degrees:—

Doctor of Medicine.—Arthur Frederick Shoyer, B.A., B.C., Trinity Hall.

Bachelor of Medicine and Bachelor of Surgery.—Arthur Croft Hill, M.A., Trinity College; Francis John Nicholls, St. John's College.

Bachelor of Medicine.—Richard Ernest Sedgwick, B.A., B.C., Gonville and Caius College.

The degree of M.A. *honoris causâ* is to be conferred on Dr. G. H. F. Nuttall, Lecturer in Bacteriology and Preventive Medicine, and on Mr. T. Strangeways Pigg, M.R.C.S. Eng., Demonstrator of Pathology.—The Special Board for Medicine have had under their consideration the question of re-arranging the subjects of the Third Examination for the M.B. degree, and have prepared a report showing how the subjects of this examination may be brought into better educational sequence.

Society of Apothecaries of London.—In November the following candidates passed in the subjects indicated:—

Surgery.—J. H. Beasley (Sections I. and II.), Birmingham; A. H. Brehaut (Section I.), Cambridge and King's College Hospital; J. H. Clements University College Hospital; M. E. Fendick (Sections I. and II.), Royal Free Hospital; J. I. Halstead (Section I.), Manchester; D. J. Morgan (Sections I. and II.), St. Mary's Hospital; J. C. S. Rashleigh (Section II.), St. George's Hospital; A. T. Spanton (Section II.), Cambridge and St. George's Hospital; and V. F. Wall (Section I.), St. Mary's Hospital.

Medicine.—R. V. Cowey (Sections I. and II.), St. Mary's Hospital; E. N. de V. Dawson (Section I.), St. Thomas's Hospital; R. A. Jones (Section I.), St Mary's Hospital; J. C. S. Rashleigh (Sections I. and II.), St. George's Hospital; and A. T. Spanton (Sections I. and II), Cambridge and St. George's Hospital.

Forensic Medicine.—A. H. Bell, Cork and Guy's Hospital; R. V. Cowey, St. Mary's Hospital; M. E. Fendick, Royal Free Hospital; R. A. Jones, St. Mary's Hospital; D. E. Lockwood, Royal Free Hospital; J. C. S. Rashleigh, St. George's Hospital; F. A. Segreda, Guy's Hospital; and P. Southan, Birmingham.

Midwifery.—A. G. H. Anthonisz, University College Hospital; L. Bradstock, Birmingham; A. H. Brehaut, Cambridge, and King's College Hospital; A. C. Clarke, Manchester; E. Courtauld, Royal Free Hospital; J. W. Elliott, St. Mary's Hospital; M. E. Fendick and R. Gillett, Royal Free Hospital; D. T. Jones, Middlesex Hospital; O. Millauro, Westminster Hospital; D. J. Morgan, St. Mary's Hospital; and B. Rowlands, St. Bartholomew's Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: A. C. Clarke, R. V. Cowey, J. C. S. Rashleigh, and A. T. Spanton.

Royal College of Surgeons in Ireland: Fellowship Examination.—The following gentlemen having passed the necessary examination have been admitted Fellows of the College:—

M. A. Brennan, L.R.C.S. Irel.; T. I. Considine, L.R.C.S. Irel.; O'C. J. Delahoyde, L.R.C.S. Irel.; W. R. G. Hamilton, L.R.C.S. Irel.; R. J. Harvey, L.R.C.S. Irel.; E. S. Hawthorne, L.R.C.S. Irel.; C. A. Hayman, L.R.C.S. Irel.; N. J. Keller, L.R.C.S. Irel.; G. Q. Lennane, L.R.C.S. Irel.; J. McGinn, L.R.C.S. Edin.; M. J. C. Marmion, L.R.C.S. Irel.; A. B. Mitchell, B.Ch. Roy. Univ. Irel.; F. Nolans, L.R.C.S. Irel.; E. M. J. O'Farrell, L.R.C.S. Irel.; W. Pooley, L.R.C.S. Irel.; D. Power, L.R.C.S. Irel.; H. Ross-Todd, L.R.C.S. Irel.; E. C. Ryall, L.R.C.P. Lond.; J. Trant, L.R.C.S. Irel.; R. S. Wayland, L.R.C.S. Irel.; and A. E. Wynne, L.R.C.S. Edin.

The following gentleman passed the primary part of the examination:—

M. Malone-Lee.

Medical Magistrate.—Mr. Samuel P. Smith, L.R.C.P., L.R.C.S. Irel., has been appointed by the Lord Chancellor a magistrate for the borough of Croydon.

Asylum Accommodation in Cornwall.—At the last meeting of the Penzance Board of Guardians it was stated that the Cornwall County Asylum was now full. The guardians, who had a patient waiting to be removed to the asylum, decided to petition the county council to provide more accommodation at the institution.

Superannuation Allowance.—At the meeting of the Swansea Board of Guardians held on Nov. 15th it was stated that the Local Government Board had agreed to a five years' extension of the term of service of Mr. David Howell Thomas, medical officer to the Swansea Workhouse, so as to permit of his retirement upon the full superannuation allowance.

THE annual conversazione of the Royal British Nurses' Association will be held at Westminster Town-hall on Tuesday next, Dec. 4th, at 8 P.M.

HOSPITAL SUNDAY AT PLYMOUTH.—Oct. 21st was observed in Plymouth as Hospital Sunday, when £690 were collected in the various churches and chapels for the South Devon and East Cornwall Hospital, Plymouth.

BEQUEST.—The Treasurer of the British Medical Benevolent Fund has received the sum of £1000, free of legacy duty, from the executors of the late Mr. Manwaring Shurlock, M.R.C.S. Eng., L.S.A., of Chertsey.

THE DESTRUCTION OF HUNTER'S HOUSE.—The dismantlement of No. 28, Leicester-square, which is now taking place in consequence of a large improvement scheme in the locality, is interesting from the fact that it is the house at the rear of which John Hunter built his famous museum of comparative anatomy.

STOCKPORT AND DISTRICT MEDICAL SOCIETY.—The following resolution was unanimously passed at a special meeting of the above society held on Nov. 22nd :—

> That this meeting of medical practitioners of Stockport and neighbourhood indignantly protest against the ignorant and insulting paragraph contained in the *Cheshire County News* of the 16th inst. in which invidious comparison is made between a notorious quack and registered medical practitioners.

The passage in the *Cheshire County News* ran as follows :—

> In reference to the decision arrived at by a Yorkshire coroner's jury affecting Dr. Rawlings of Reddish it will be of interest to learn that Dr. Rawlings has since been the recipient of numerous letters from old patients and others expressing their sympathy with him, their confidence in his ability, and admiration for his character. At a meeting also the other night in a room crowded with men Dr. Rawlings fulfilled an engagement to lecture, and a most remarkable manifestation of sympathy with the medical gentleman broke out, the cheering being loud and long-continued. We need only add that an unregistered medical practitioner, however able he may be, is subject to disagreeable incidents similar to that in which Dr. Rawlings is involved, while men with not half his ability, if registered, would escape them altogether.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL PROVIDENT LEAGUE

WE have received from a considerable number of correspondents inquiries concerning a body to be called the Medical Provident League From a preliminary circular which is stated to be addressed to "medical practitioners who now attend members of the National Deposit Friendly Society we learn that the objects and constitution of the league are as follows:—

Objects

1 To unite medical practitioners throughout the United Kingdom for the better defence and furtherance of their professional interests

2. To bring about better arrangements for affording provident medical aid to the working classes

3 To support such existent provident schemes as are equitable to medical practitioners and to oppose such schemes as are inequitable in their working or management.

4 To unite and coördinate the personal influence of medical practitioners with individual Members of Parliament in order to direct the course of any legislation which affects the interest of the medical profession or of the public health

5 To initiate, or support, schemes incidental to, or conducive to, the furtherance of the above objects

Constitution

1 Membership of the League shall be open to any registered medical practitioner

2. The members, in annual general meeting, shall elect such officers as may from time to time seem desirable and a Council to manage the affairs of the League

3 The subscription for Foundation Members shall be half a guinea entrance fee and half a guinea annual subscription All entrance fees shall be invested in Trustee Securities and set aside as a permanent Reserve Fund

This information concerning the Medical Provident League is prefaced by the following letter —

245, Kennington road, London, S E, November 1st, 1900

MY DEAR SIR,

You are aware of the universal dissatisfaction throughout our profession with the methods and management of the Medical Aid Associations and similar bodies, how they are, to an ever increasing extent overworking and underpaying their Medical Officers, how powerless our disunited ranks seem to be to cope with the growing evils of the system: how our appeals for restrictive enactments have been made, in vain to Councils and Colleges

It is strongly felt that we must do as Englishmen have always done—HELP OURSELVES and trust to our own efforts to combat the grave abuses of which we complain The first essential is union· and it has been therefore determined to establish a MEDICAL PROVIDENT LEAGUE as an active fighting and political organisation fighting the Medical Aid Associations, on their own ground, by giving every support to Provident Societies which will pay their medical officers fairly and treat them with the courtesy and respect which are due to members of a skilled and honourable profession, persuading one Society after another to adopt that attitude, moreover, uniting and co-ordinating the personal influence of medical men with individual members of Parliament so as to obtain due attention to our professional interests in all new legislation, and especially to secure proper payment for all medical services rendered to the State, e g, payments *for Certificates of Death*

A commencement has now been made in the fulfilment of the above programme After prolonged consideration and negotiation the following Resolutions have been brought before, and unanimously passed by, the governing body of the NATIONAL DEPOSIT FRIENDLY SOCIETY

(Membership, about 50 000 Invested Funds, about £250 000)

"The GENERAL COMMITTEE of the NATIONAL DEPOSIT FRIENDLY SOCIETY, which now works in the most harmonious and satisfactory manner with several hundred MEDICAL PRACTITIONERS throughout the Country, is sincerely desirous to receive the active support and confidence of the MEDICAL PROFESSION generally, and, in particular, to accord to any representations which the Medical Officers of the Society might desire to make the fullest consideration and respect It is, therefore, hereby RESOLVED:—

(1) That the General Committee of the National Deposit Friendly Society would welcome the formation of an Association of medical practitioners willing to attend Members of the Society upon the terms and conditions specified in the Rules of the Society.

(2) That, if such a Medical Association were formed, the General Committee would be prepared to co-opt, as acting members of the General Committee, two medical practitioners, to be nominated each year by the said Association, so that these *gentlemen could represent the views and wishes of its Medical* Officers upon the Governing Body of the said Society

(3) That the said Society being about to appoint—as every other Insurance Company does—special Medical Referees to examine Applicants for Life Assurance (the new Department to be opened by this Society on January 1st next), the General Committee would be prepared to receive the Nominations of such Referees if made by the said suggested Association"

In brief, then, this Society, which is highly *spoken of by* all who have worked for it, offers, in return for moral support from a medical association to give that association a voice in the management of its affairs by direct representation on its governing body; and to give it also a valuable *quid pro quo* by the power of nominating the practitioners who shall be appointed as MEDICAL REFEREES for the new LIFE INSURANCE DEPARTMENT of the Society These appointments as you are doubtless aware, will probably be very lucrative, *and every member of the League would of course, be eligible for nomination.*

(*In future, as at present any member of the Society can consult any medical practitioner he chooses, for sickness or injury The Society merely offers valuable appointments for special Insurance work to those practitioners who will combine to give their associated aid and support to the Society*)

It will be admitted that these concessions are wise and generous and prove the desire of this Society to stand well with the Medical *Profession It is obvious that they represent a strong foundation* for the future work and success of the Medical Provident League (*vide* next page), and a remarkable encouragement to practitioners to unite together to help both themselves and their profession

All the preliminary steps have been taken and cordial promises of help have been received It is therefore proposed to found the MEDICAL PROVIDENT LEAGUE and to enrol members at once, to elect the Officers and the Council as speedily as possible, *in order to nominate members as Referees for every district Immediate action is necessary, as those appointments must be settled in the next month*

Under the circumstances, it is felt that, in the formation of the League, the offer of membership and its great practical advantages should be *first* made to medical practitioners who now attend members of the National Deposit Friendly Society, and I therefore address this preliminary circular to you, feeling confident that you will recognise the practical value of membership to yourself and *afford us your co-operation and* aid

To avoid the financial mistake, made by most Medical Societies in the past an Entrance Fee of half a guinea besides an Annual Subscription of half a guinea, for FOUNDATION MEMBERS, has been decided upon, and the former amounts will be invested in Trustee securities as a Reserve Fund It is probable in view of the practical value of membership, that *both the Entrance Fee and the Annual Subscription will be considerably increased for future members*

If you will fill up and return to me the appended form, your name shall be enrolled as a Foundation Member of the League, and further circulars will be sent you at once If you do not reply, it will be assumed that you do not desire to join the movement

I am, Dear Sir,
Yours faithfully,
J W J OSWALD, M D,
Chairman of the Organising Committee

Dr Oswald's letter incloses the following post-card addressed to himself

The Secretary, The Medical Provident League

SIR —I request you to place my name on the list of Foundation *Members of the* Medical Provident League and as soon as the League is formed I will forward you Cheque for One Guinea, being an Entrance Fee of half a guinea and my first Annual Subscription *of half a* guinea

Qualifications

Please write very distinctly
Signed
Address
November 1900

PLEASE ANSWER THE FOLLOWING QUESTIONS

Would you desire to be nominated for election as a Medical Insurance Referee of the National Deposit Friendly Society?

Would you act, if elected, as Local Secretary of the League in your District?

Would you act on the General Council of the League, if elected thereon?

We have given so much space to the printing of this circular, without abbreviation, because we have to offer unfriendly criticism of the proposals which it contains It is because we, like the gentlemen whom Dr Oswald addresses, "are aware of the universal *dissatisfaction* throughout our profession with the methods and management of the Medical Aid Association and similar bodies," and are aware, also, how well grounded this dissatisfaction is, that we *feel* bound to warn our readers that the league holds out nothing which should induce them to join it. The circular is a proposal *for a bargain* to be struck between medical men and a friendly society The National Deposit Friendly Society desires "moral support from a medical association" The General Committee

Eadie, James, M.B., Ch.B. Melb., has been appointed Public Vaccinator for Balaclava, Victoria, Australia.

Royal Ear *Hospital*, Soho, London.—House Surgeon (non-resident) Small honorarium given.

Royal Hants County Hospital, Winchester.—House Surgeon, unmarried. Salary £65 per annum, rising to £75, with board, residence, &c.

Royal Hospital for Incurables, Donnybrook, Dublin.—Resident Medical Officer for one year. Salary £100 per annum, with board and furnished apartments.

Royal National Mission to Deep Sea Fishermen's Hospital Vessels.—Young Medical Officer for service. Salary £3 3s. weekly. Apply to Mr. F. H. Wood, 181, Queen Victoria-street, London.

Seamen's Hospital Society ("Dreadnought"), Greenwich, S E.—House Physician for "Dreadnought" Hospital. Salary £75 per annum, with board and residence.

The Chief Inspector of Factories gives notice of vacancies as Certifying Surgeons under the Factory Acts at Banbridge, in the county of Down; at Dorking, in the county of Surrey; at Walton-on-the-Naze, in the county of Essex; and at Halesworth, in the county of Suffolk.

Throat Hospital, Golden-square, London.—Non-resident Junior House Surgeon. Salary £100 per annum, with luncheon daily.

University College, London.—Assistant Surgeon.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser, who shall be also Assistant Secretary, for two years, unmarried. Salary £100 per annum, with furnished rooms, board, fire, lights, attendance, and washing.

West London Hospital, Hammersmith-road, W.—House Physician and House Surgeon, for six months. Board and lodging provided.

Births, Marriages, and Deaths.

BIRTHS.

Davis—On Nov. 23rd, at Grand-parade, St. Leonards, Dorothy, wife of W. H. Davis, M.B., M.R C P., of a daughter.

Jones.—On Nov. 25th, at Mayo, Llangammarch Wells, Breconshire, the wife of W. Black Jones, M.D., B S, of a daughter (stillborn)

Newton—On Nov. 14th, at Balcombe, Sussex, the wife of Reginald Newton, M.R C.S., L.R.C.P., of a son.

MARRIAGES.

Elwin—Graves.—On Nov. 24th, at St. Alphege's, Greenwich, George Richard Elwin, M D., of Brook House, Bromley, Kent, to Beatrice, eldest daughter of James Graves, The Grove, Blackheath.

Tresidder—Garden.—On Nov. 21st, at the parish church, Dalton-in-Furness, Morton Everard Tresidder, M.R.C S., L R.C.P. Lond., of Westcombe Park, Blackheath, London, to Elsie Annie daughter of the late James Garden, Hamilton House, Dalton-in-Furness.

DEATHS.

Edwards.—On Nov. 20th, at his residence, Tynyffordd, Colwyn Bay, North Wales, Roger Edwards, M.D. Durham, M.R.C.S. Eng., L.R.C.P. Lond., in his 50th year.

Neale.—On Nov. 22nd, Richard Neale, M.D. Lond., of South Hampstead and Sandgate, Kent, aged 73.

Rawdon.—On Nov. 22nd, at Underbank, Elstree, Herts, suddenly, Henry Greenwood Rawdon, M.D., F.R.C.S. Edin., aged 63 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL PROVIDENT LEAGUE.

WE have received from a considerable number of correspondents inquiries concerning a body to be called the Medical Provident League. From a preliminary circular which is stated to be addressed to "medical practitioners who now attend members of the National Deposit Friendly Society we learn that the objects and constitution of the league are as follows:—

Objects

1. To unite medical practitioners throughout the United Kingdom for the better defence and furtherance of their professional interests.

2. To bring about better arrangements for affording provident medical aid to the working classes.

3. To support such existent provident schemes as are equitable to medical practitioners and to oppose such schemes as are inequitable in their working or management.

4. To unite and coördinate the personal influence of medical practitioners with individual Members of Parliament in order to direct the course of any legislation which affects the interest of the medical profession or of the public health.

5 To initiate, or support, schemes incidental to, or conducive to, the furtherance of the above objects.

Constitution.

1. Membership of the League shall be open to any registered medical practitioner.

2. The members, in annual general meeting, shall elect such officers as may from time to time seem desirable and a Council to manage the affairs of the League.

3. The subscription for Foundation Members shall be half a guinea entrance fee and half a guinea annual subscription. All entrance fees shall be invested in Trustee Securities and set aside as a permanent Reserve Fund.

This information concerning the Medical Provident League is prefaced by the following letter:—

245, Kennington-road, London, S E, November 1st, 1900.

MY DEAR SIR,

You are aware of the universal dissatisfaction throughout our profession with the methods and management of the Medical Aid Associations and similar bodies; how they are, to an ever-increasing extent, overworking and underpaying their Medical Officers; how powerless our disunited ranks seem to be to cope with the growing evils of the system; how our appeals for restrictive enactments have been made, in vain, to Councils and Colleges.

It is strongly felt that we must do as Englishmen have always done—HELP OURSELVES; and trust to our own efforts to combat the grave abuses of which we complain. The first essential is union; and it has been therefore determined to establish a MEDICAL PROVIDENT LEAGUE as an active fighting and political organisation; fighting the Medical Aid Associations, on their own ground, by giving every support to Provident Societies which will pay their medical officers fairly and treat them with the courtesy and respect which are due to members of a skilled and honourable profession; persuading one Society after another to adopt that attitude; moreover, uniting and co-ordinating the personal influence of medical men with individual members of Parliament so as to obtain due attention to our professional interests in all new legislation, and especially to secure proper payment for all medical services rendered to the State; e g, payments for Certificates of Death.

A commencement has now been made in the fulfilment of the above programme. After prolonged consideration and negotiation the following Resolutions have been brought before, and unanimously passed by, the governing body of the NATIONAL DEPOSIT FRIENDLY SOCIETY.

(Membership, about 50,000 Invested Funds, about £250,000.)

"The GENERAL COMMITTEE of the NATIONAL DEPOSIT FRIENDLY SOCIETY, which now works in the most harmonious and satisfactory manner with several hundred MEDICAL PRACTITIONERS throughout the Country, is sincerely desirous to receive the active support and confidence of the MEDICAL PROFESSION generally, and, in particular, to accord to any representations which the Medical Officers of the Society might desire to make the fullest consideration and respect. It is, therefore, hereby RESOLVED:—

(1) That the General Committee of the National Deposit Friendly Society would welcome the formation of an Association of medical practitioners willing to attend Members of the Society upon the terms and conditions specified in the Rules of the Society.

(2) That, if such a Medical Association were formed, the General Committee would be prepared to co-opt, as acting members of the General Committee, two medical practitioners, to be nominated each year by the said Association, so that these gentlemen could represent the views and wishes of its Medical Officers upon the Governing Body of the said Society.

(3) That the said Society being about to appoint—as every other Insurance Company does—special Medical Referees to examine Applicants for Life Assurance (the new Department to be opened by this Society on January 1st next), the General Committee would be prepared to receive the Nominations of such Referees if made by the said suggested Association."

In brief, then, this Society, which is highly spoken of by all who have worked for it, offers, in return for moral support from a medical association, to give that association a voice in the management of its affairs by direct representation on its governing body; and to give it also a valuable *quid pro quo* by the power of nominating the practitioners who shall be appointed as MEDICAL REFEREES for the new LIFE INSURANCE DEPARTMENT of the Society. These appointments, as you are doubtless aware, will probably be very lucrative, and every member of the League would, of course, be eligible for nomination.

(In future, as at present, any member of the Society can consult any medical practitioner he chooses, for sickness or injury Th Society merely offers valuable appointments for special Insurance work to those practitioners who will combine to give their associated aid and support to the Society.)

It will be admitted that these concessions are wise and generous and prove the desire of this Society to stand well with the Medical Profession. It is obvious that they represent a strong foundation for the future work and success of the Medical Provident League (*vide* next page), and a remarkable encouragement to practitioners to unite together to help both themselves and their profession.

All the preliminary steps have been taken and cordial promises of help have been received. It is, therefore, proposed to found the MEDICAL PROVIDENT LEAGUE and to enrol members at once; to elect the Officers and the Council as speedily as possible, *in order to nominate members as Referees for every district. Immediate action is necessary, as those appointments must be settled in the next month*

Under the circumstances, it is felt that, in the formation of the League, the offer of membership and its great practical advantages should be *first* made to medical practitioners who now attend members of the National Deposit Friendly Society, and I therefore address this preliminary circular to you, feeling confident that you will recognise the practical value of membership to yourself and afford us your co-operation and aid.

To avoid the financial mistake, made by most Medical Societies in the past, an Entrance Fee of half a guinea, besides an Annual Subscription of half a guinea, for FOUNDATION MEMBERS, has been decided upon, and the former amounts will be invested in Trustee securities as a Reserve Fund. It is probable, in view of the practical value of membership, that *both the Entrance Fee and the Annual Subscription will be considerably increased for future members.*

If you will fill up and return to me the appended form, your name shall be enrolled as a Foundation Member of the League; and further circulars will be sent you at once. If you do not reply, it will be assumed that you do not desire to join the movement.

I am, Dear Sir,
Yours faithfully,
J. W. J OSWALD, M.D.,
Chairman of the Organising Committee.

Dr. Oswald's letter incloses the following post-card addressed to himself.

The Secretary, The Medical Provident League.

SIR,—I request you to place my name on the list of Foundation Members of the Medical Provident League, and as soon as the League is formed I will forward you Cheque for One Guinea, being an Entrance Fee of half a guinea, and my first Annual Subscription of half a guinea.

Qualifications

Please write very distinctly.
Signed ....
Address ....
November .... 1900.

PLEASE ANSWER THE FOLLOWING QUESTIONS.

Would you desire to be nominated for election as a Medical Insurance Referee of the National Deposit Friendly Society? ....

Would you act, *if elected, as Local Secretary* of the League in your District?... ....

Would you act on the General Council of the League, if elected thereon?..... ... .

We have given so much space to the printing of this circular, without abbreviation, because we have to offer unfriendly criticism of the proposals which it contains. It is because we, like the gentlemen whom Dr. Oswald addresses, "are aware of the universal dissatisfaction throughout our profession with the methods and management of the Medical Aid Association and similar bodies," and are aware, also, how well grounded this dissatisfaction is, that we feel bound to warn our readers that the league holds out nothing which should induce them to join it. The circular is a proposal for a bargain to be struck between medical men and a friendly society. The National Deposit Friendly Society desires "moral support from a medical association." The General Committee of the National Deposit Friendly Society "is sincerely desirous to receive the active support and confidence of the medical profession." In other words, the National Deposit Friendly Society will be much obliged if medical men will combine together to act as canvassers for the society. There is no doubt of the value that such support would be to the society. What are the medical men to receive in return? Membership of a league, which they could certainly found and manage for themselves, if they saw it was needed, without the embarrassing assistance of a friendly society; and eligibility for nomination as medical referees to a life insurance scheme which has not yet been started. We think that the National Deposit Friendly Society would have all the best of the bargain and we advise our readers to refrain from filling up the card.

We are sorry to write in an antagonistic spirit to a scheme which on the face of it is an attempt to reconcile a well-managed friendly society—as we believe the National Deposit Friendly Society to be—with the medical profession. But the olive branch must be tendered in a very different way. Medical men must not be invited to act as local secretaries to a body affiliated to a friendly society, for a local secretary who does not canvass for his association is an idle name, while a local secretary who does his duty has necessarily to be a tout. (We do not use the word in an offensive sense.) If the National Deposit Friendly Society is genuinely anxious to work hand-in-hand with the medical profession we can tell it how to begin. It should co-opt as acting members of its General Committee representatives chosen by several hundred of the medical practitioners "with whom it now works in the most harmonious and satisfactory manner," and should take their views as to the rate of remuneration for medical service and the wage limit above which medical service cannot be rendered. There are other things that might be discussed in a general committee so constituted that medical interests could be properly looked after, but the two points which we have mentioned would be good ones upon which to begin.

"THE REMOVAL OF SUPERFLUOUS HAIRS."

To the Editors of THE LANCET.

SIRS,—Your correspondent "Bath" in THE LANCET of Oct. 20th, 1900, will find a recently prepared sulphuret of calcium effective in the removal of hairs. The sulphuret of calcium is easily prepared by passing sulphuretted hydrogen through milk of lime until the colour of the lime changes to a bluish tint. After a few weeks the preparation becomes weakened, due probably to the gradual oxidation of the sulphuret. I am, Sirs, yours faithfully,

Nov. 16th, 1900. J. J. R.

"MOTOR-CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—Kindly allow me to say a few more words on the above subject and I will not further trouble you. First, Mr. Truman, so far as I can gather, has not said a word in support of the motor-cars for medical men's use. Secondly, the subject is not a "foreign" one to your columns as my remarks were entirely confined to the utility of motor-cars for medical men at the present time and not for general purposes. Thirdly, an art critic need not necessarily be a practical painter. Fourthly, the "man in the street" often has a shrewder notion of things in general than he is credited with.

I am, Sirs, yours faithfully,

Nov. 12th, 1900. MOTOR CAR.

NEW EDITIONS OF SCIENTIFIC WORKS.

To the Editors of THE LANCET.

SIRS,—Every week almost sees new editions of general text-books and books on special subjects It would be a great boon to many practitioners who, like myself, cannot afford to keep throwing away the older editions and investing in the latest and yet desire to keep up-to-date, if authors and publishers when issuing a new edition could see their way to publish an appendix giving the alterations and additions of such work. They would not be likely to lose by it, as those who can afford it would still buy the complete work, while the appendix would appeal to a wider circle. May I ask for your powerful support of this appeal? I am, Sirs, yours faithfully,

Nov. 19th, 1900. APPENDIX.

THE LATE HARMAN JOHN TARRANT.

WE have received another letter calling our attention to the advertising methods of this unfortunate man. Tarrant died early in September in Sydney—a fact which we have learned since our last publication of reflections upon his actions.

A POINT IN ETHICS.

To the Editors of THE LANCET.

SIRS,—A and B are friendly practitioners in the same town. C is well known to both. During A's absence on holiday C sends for B because he does not wish to have the services of A's assistant whom he well knows. B tells C that he attends for A and that A must be informed of it when he returns. C agrees to this, but does not inform him. The day after A returns more medicine is sent for from B, which he declines to supply, sending a note that his attendance was for an emergency and that now, A having come home, C must apply to him. Subsequently A and B meet and the matter is mentioned by B, but A seems annoyed and says that C ought to have known better—in fact, almost blames B for going. Three months afterwards C again sends for B and says he wants him to attend and remarks that he is going to have what doctor he likes. Ought B in these circumstances to attend, and can A blame him for taking the case when C palpably wants to change his medical attendant?

I am, Sirs, yours faithfully,

Nov. 26th, 1900. NEMO.

*** B can attend C without infringing medical etiquette, but he should point out to C that such changes in medical attendance often lead to unpleasantness. It is sincerely to be hoped that A will not allow the matter to alter the harmonious relations between him and B.—ED. L.

"THE BATTLE OF THE CLUBS: A SUCCESSFUL PRECEDENT."

To the Editors of THE LANCET.

SIRS,—Under the above heading I read with much interest the annotation in THE LANCET of Nov. 24th, p. 1514, *re* the "Eastbourne Provident Medical Association" and its success. There is one point which to my mind is of great importance, and on which I should be glad of information—viz., How is the collector paid? Whether a fixed salary, or by commission, or part commission? For if either of the latter two it is obviously to his interest to cause as many persons as possible to join the association. In which case "collector" and "canvasser" are undoubtedly synonymous terms. A collector is quite as much human nature as a canvasser, and instructions to him not to canvass are futile, and in fact childish.

I am, Sirs, yours faithfully,

Ilford, Nov. 27th, 1900. C. B. TOWNSHEND.

THE PARKES MEMORIAL PRIZE.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you will inform me through the medium of your paper the conditions of award of the Parkes Memorial Bronze Medal. I am, Sirs, yours faithfully,

Nov. 9th, 1900. DWARF.

*** The Parkes Memorial Prize is awarded triennially. It consists of a bronze medal and a sum of 75 guineas. The competition is open to executive officers on full pay of the Navy, Army, and Indian medical services, except assistant professors at Netley who are not eligible to compete during their term of office. Application should be made to the secretary, Parkes Memorial Committee, Royal Victoria Hospital, Netley.—ED. L.

CLARATMOS.

To the Editors of THE LANCET.

SIRS,—Permit me to correct a mistake which has inadvertently been inserted in THE LANCET of Nov. 24th, page 1508, *re* "Claratmos Patent Ventilating Screen." Messrs. F. W. Warren and Co. are described as the patentees, whereas I am the patentee and Messrs Warren and Co. are the manufacturers. I have used the screen in my own house and have found it invaluable, inasmuch as it admits air without impurities, a point of no small importance during the foggy winter season.

I am, Sirs, yours faithfully,

South Kensington, S.W., Nov. 26th, 1900. CALDWELL STEPHEN.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them. Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their *subscriptions* direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

The Harveian Lectures

ON

PROGNOSIS AND TREATMENT IN PULMONARY TUBERCULOSIS.

Delivered before the Harveian Society of London on Nov. 1st, 8th, and 15th, 1900,

BY ROBERT MAGUIRE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL.

LECTURE II.[1]

Delivered on Nov. 8th, 1900.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I discussed with you how the prognosis of tuberculosis of the lungs in the first stage of its course, that of "invasion," may be judged from the physical signs and the localisation of the lesions, and I considered, also, what effect pre-existent affections might have upon the future of the patient. Let us now pass on to the indications which may be given to us by individual symptoms and complications, still confining our discussion to the "first stage." The symptoms accompanying this stage are many and all are at times important for diagnosis, but those which help us in prognosis are but few, and they may be classified under the heads of Pyrexia, General Weakness, Digestive Disturbances, and Hæmoptysis. I have mentioned how the conditions previously considered require care in their estimation before one can found a prognosis upon them. But still more is this necessary in the case of symptoms. Not one of them alone is of much value, but I must point out to you how, when combined together or with the other conditions, they may be of some assistance. Pyrexia may be entirely absent, even though the temperature in a doubtful case be taken every four hours. So much, one might say, the better for the patient. So much the better, too, might we think the matter if there were but few physical signs, and those, too, limited to one particular area. But caution must be observed here. Such a state of things may be merely the result of a lack of reactionary power on the part of the general system, a lack of protective power; and if together with the conditions named there be tubercle bacilli in the sputum and extreme general weakness we can only consider the condition as very grave and indicating an unresisted attack of the bacillus. In no short time one frequently meets with a furious outbreak and rapid destruction of lung tissue.

But given bacilli in the sputum and little or no pyrexia, the local manifestation limited, but with the general strength well maintained, the prognosis is good. The indications are that the attack is not powerful, the resistance to it is good and not fully called forth. For we should, let me remind you, consider the fever as the result either of bacillary poison or, on the other hand, of inflammatory chemiotaxic reaction. It is impossible to entirely differentiate the two, but I would provisionally put it to you that the maintenance of body strength, together with the presence of localised physical signs and the lack of marked pyrexia, would indicate a healthy reaction, while, on the other hand, localised and even very limited physical signs, with lack of marked pyrexia but with great diminution of physical strength, would show a lack of resistance to the bacillus, not only on the part of the lung, but on that of the whole general system.

Yet, leaving the question of maintenance of general strength out of the discussion, one may roughly say that the higher the pyrexia the worse the prognosis in this stage, and *vice versâ*. And yet once more we must use caution, especially with neurotic patients. Such patients may show a very high temperature when there is really nothing much wrong with them, and in the absence of physical signs their condition is very confusing. Nothing but great experience can prevent the physician from being led into error in diagnosis by such a physical state, and the same error is easily made in prognosis. It happens not infrequently that tuberculosis of the lungs, like enteric fever, may have a most turbulent outbreak and very soon lapse into a very ordinary mild and tractable attack. Now, my colleague, Dr. Kingston Fowler, has shown that the only form of pyrexia which can be absolutely said to be tuberculous is that in which the morning temperature is higher than that of the evening. For the diagnosis of pulmonary and other forms of tuberculosis there cannot be any question of the value of this observation, and especially when other indications are doubtful. For prognosis too, this sign may be of use as indicating a very pronounced tuberculous poisoning. On this point even the large record of out-patient cases which I have used cannot help us, and we must appeal for facts to the in-patient department. Since taking the charge of in-patients I have paid special attention to the matter, and at present for convenience of observation the evening temperature is marked on the charts in red and the morning temperature in black. It is very remarkable, however, how very rarely in the course of a case of pure tuberculosis this sign appears. Nor is this to be wondered at when we remember the many known causes of the pyrexia. Tuberculous infection and its accompanying tissue reaction or chemiotaxis are, in the first stage, causes of fever. Whereas later we have added to them poisoning by the staphylococcus and pneumococcus. Pyrexia due to tuberculous poison alone must necessarily be rare and not always is it of the reversed type. Therefore, it must be only seldom that the pyrexial condition can help us in prognosis. But somewhat approaching this type is a pyrexia in which the morning temperature never reaches the normal, albeit the evening temperature may be only slightly higher. Such a pyrexia, even alone as a sign, is of very unfavourable augury, and the higher the morning temperature and the nearer it approaches to the evening temperature the worse is the outlook for the patient.

In regard to the foregoing remarks it is necessary that I should say that they refer to temperatures taken in the mouth. For really scientific results one should place the thermometer in the rectum and this is done now, I believe, in most of the open-air sanatoria. But in ordinary practice there are obvious objections to this method and I have striven here to give opinions which may be made use of only in ordinary practice.

General weakness at the commencement of a tuberculous attack must manifestly be harmful, and indeed, as I have hinted above, increases greatly the gravity of other symptoms. Particularly (if one may analyse the state) must weakness of cardiac and vaso-motor action be considered a bad sign. The patients who have blue and cold extremities almost invariably do badly. Nor does this remark contradict what I have previously said as to the occasionally bad prognosis to be given to florid subjects, for often that florid appearance is a sign of vaso-motor weakness and not of a healthy circulation. This feebleness of circulation, and with it of the general system, carries with it a bad prognosis, not only because it indicates a prospective lack of resistance of the tissues to the tuberculous poison, but also because it usually interferes greatly with such valuable means of cure as over feeding and residence in high altitudes and the open-air, valuable as at times these remedies may be in counteracting this very condition. The same must be said of digestive disturbances accompanying an attack. They interfere with the application of systematic treatment. But I should like also to say a few words about the prognosis of cases which show gastric derangement as their first symptom. It has long been known that an irritation of the pneumogastric nerve endings in the lungs may first show itself by a reflex irritation of the endings of the same nerve in the stomach. The diagnosis of such an occurrence is often very difficult, since even for some little time the lung lesion may be so slight as to be indiscoverable on the most careful examination. But sooner or later the lung lesion does show itself, and in my experience such cases eventually do badly.

Let us now turn, however, to one of the best known of the symptoms which accompany the earlier stages of pulmonary tuberculosis—namely, hæmoptysis. This symptom is only too well known and causes far too much alarm. Yet it occurs so often in other disorders that I think one may say that hæmoptysis alone is most frequently not caused by lung disease. But given that it actually is produced by lung disease in the earlier stages, life to be accompanied by signs of lung mischief. 2. Always post-mortem laryngeal tuberculosis is accompanied by lung lesions. 3. Advanced lesion of the larynx may be accompanied by but slight lesion of the lungs and yet the former may be secondary and the latter primary. 4. The non-finding of lung trouble is no proof of its non-existence, for even the best observers may be deceived in this matter.

---

[1] Lecture I. was published in THE LANCET of Dec. 1st, 1900, p. 1549

As an illustration of the latter argument I may mention a case which occurred in the out-patient department of the Brompton Hospital. A man presented himself one day who had unquestionable tuberculous ulceration of the larynx. He had also cough and all the appearances and symptoms of advanced tuberculosis of the lungs. But the most careful examination by myself and several other medical men who were attending the clinique, failed to find any but the most ambiguous physical signs in the chest. This might have been looked upon as a case of primary laryngeal tuberculosis, yet I was sure it could not be. On two other occasions, an interval of a fortnight elapsing between his visits, his chest was further examined and with the same result. But on his fourth attendance signs of cavity were found in almost every portion of the thorax. The cavities could not have formed in a fortnight. Undoubtedly they were present at his first examination but, from blocking by mucus or from some other condition, escaped detection.

Tuberculosis of the larynx is therefore always caused by infection of the larynx through the excretion of the lungs Similarly, too, the intestines become infected from the swallowing of tuberculous sputum I do not speak here of primary tuberculosis of the intestines, which is most common in children, but of the intestinal ulceration secondary to lung disease. That this is due to infection carried from above is shown by its localisation. It is invariably seen in its early stages near the ileo-cæcal valve. During my period of office as pathologist to the Brompton Hospital, Dr. Dodgson and Dr. Soltau Fenwick examined carefully the appendix vermiformis in all the post-mortem examinations. They always found it to be affected when other parts of the intestines were ulcerated and in a not inconsiderable number of cases they found the appendix alone to be affected. This points to the conclusion that the ulceration occurs where the swallowed secretions of the lung are allowed the longest contact with the mucous membrane of the bowel. The symptoms, of course, are those with which you are well acquainted—pain and diarrhœa, &c. The occurrence of this condition carries with it the gravest prognosis, and, indeed, nearly always introduces the fatal end.

As regards symptoms, there are only two which in this stage help us greatly in prognosis, and they are pyrexia and hæmoptysis. This, the second stage, is, unlike the first stage, never without pyrexia, and what has been said of the fever of the first stage applies also to that of the second stage, though without the limitations there mentioned; that the higher the fever, and again the more nearly the morning temperature approaches that of the evening, and the worse is the prognosis, may be taken as a general rule. But still worse is the so called "hectic" fever, where a morning temperature below normal is followed by an evening temperature of even eight degrees higher. This is a most serious condition and all the more so because, in my experience, no drug has the slightest effect upon it.

Hæmoptysis is a much graver symptom in the second stage than in the first, and is here dangerous. This results from the fact that while the hæmoptysis may still be caused by mere congestion, yet it much more frequently is due to ulceration of a blood-vessel from so-called caseous or suppurative arteritis. The dangers of its occurrence are: (1) loss of blood, a very serious matter in an already debilitated subject; (2) shock with cardiac failure; and (3) fright. The last-mentioned danger has not often been mentioned, and yet I have seen it occur. I differentiate it from the second danger, for I have known death occur from what I could conceive must be this and no other cause when only small quantities of blood have been expectorated or found in the lung tissue after death. There are doubtless other symptoms of the second stage, such as general weakness, emaciation, profuse night-sweats, &c., which are of importance in prognosis, but they have already been mentioned in a former part of this lecture, and they can be comparatively easily controlled by treatment, therefore they do not require detailed discussion here.

The third stage of pulmonary tuberculosis I have chosen to call that of "result" and not "cavitation," as has hitherto been done, and for the reason that "cavitation" is not the only final result of the tuberculous process, though that result always means destruction of lung tissue. Cavitation is nearly always accompanied by a certain amount of fibrous thickening round the walls of the cavity, and, *cæteris paribus*, the greater the amount of fibrosis the less dangerous is the presence of the cavity. But we may get fibroid change without any appreciable cavitation, and these two conditions, "cavitation" and "fibrosis," therefore constitute two separate forms of the "result" stage, each with its own particular elements of danger, and therefore to be distinguished in prognosis.

Pursuing again our former order of discussion we will deal first with the nature of the physical signs. The percussion note obtained over a cavity is the resultant of two conditions, the cavitation and the thickening of its walls, the one causing increased resonance, the other dulness, and hence we get the high-pitched resonance of the cavernous percussion note. Given, then, that we have diagnosed the presence of a cavity by other methods (and I have elsewhere described how this should be done), then the higher pitched the resonance the greater the resistance to the finger and the more favourable is the condition. This view is based upon the idea that such a condition of signs indicates a greater amount of fibrous tissue round the cavity, which I have above stated to be a desirable state. Moreover, the presence of "echoing" râles would indicate a complication of the third by the second stage and a further progression of tuberculous action. This, of course, is an unfavourable sign, but it must not be confused with the râles of bronchiectasis which may be present in the fibroid form of this stage. The differentiation of the two does not form part of our present subject. The localisation of the signs does not help us much in this stage, except in the respect that the more limited the area affected, naturally, the more favourable must be the prognosis. Again in this stage the influence of antecedent conditions in the prognosis need not be discussed. But one class of "individual symptoms" and complications becomes of the utmost importance. Dyspnœa, especially on exertion, but also during rest, is nearly always present and is unfavourable for prognosis. Yet its pathology and its influence on the prognosis differ in the two conditions of the stage. In the condition of cavitation the dyspnœa is due almost entirely to loss of lung tissue, and although in amount it is not usually so great as in the condition of fibrosis, yet its prognosis is more unfavourable. In the condition of fibrosis some of the dyspnœa no doubt is due to loss of lung-substance, but its greater part (as I have elsewhere shown) is caused by non-expansion of the thorax over the affected areas. The expansion of the thorax is of great importance in the sucking of blood into the heart, and if interfered with the supply of venous blood to the lungs for aeration is lessened and dyspnœa must result. But such a state is not so dangerous as is great loss of lung tissue, and consequently while the dyspnœa is greater in the fibroid than in the cavernous state its prognosis is more favourable.

In the third stage the state of the circulation and with it that of the general body condition must be carefully watched, for heart-failure is one of the most serious complications. Any sign of its appearance, such as blueness and coldness of the extremities and weakness of the heart-sounds, should place the physician on his guard. Pneumothorax, again, is a formidable complication, and while principally occurring in the third stage, may at times be found in the second stage. But its danger is, I think, mostly limited to the moment of its occurrence. Then, certainly, it may cause death from shock. But when once the shock has been recovered from I do not consider the prognosis of pneumothorax in a tuberculous lung to be so unfavourable as has been so often thought It scarcely requires treatment and often does well. Undoubtedly, like any other complication, it adds to the gravity of the condition, but lately I had four cases at one time among my in-patients at Brompton and all of them left the hospital free from pneumothorax and with their lung condition otherwise greatly improved. Pneumothorax is more common in cavitation than in fibrosis.

But hæmoptysis in this stage is a most serious matter, and its occurrence to any great amount must cause, to say the least, grave doubts of the patient's recovery. It is the greatest danger of this stage of the disease and is more frequent in the cavernous than in the fibroid state. As in the first and second stages it may be due to mere congestion or to ulceration of a vessel, but, if copious, it is most frequently caused by rupture of an aneurysm of the pulmonary artery in a cavity. I show you here what I think must be a unique collection of such aneurysms, occurring in almost every variety and with almost every form of surroundings. Their presence is a warning that percussion should always be very lightly employed, for a study of these specimens will convince you that the slightest jar of the thorax might be sufficient to cause rupture of the aneurysm. While I was pathologist at the Hospital for Consumption and Diseases of the Chest, Brompton, I only once failed to find such an aneurysm in a cavity after fatal hæmoptysis in the third stage Observe, too, that the aneurysms are often found in only small cavities, so small as to be detected only with difficulty. The aneurysms are caused by suction. During cough the air contained in the cavity is partially expelled and the cavity walls are compressed, but on the relief of the pressure the walls expand once more and before the full quantity of air can gain re-admission there is a period of negative tension in the cavity which acts as a suction power on the wall of an exposed artery. Finally, it must be remembered that for a long time, for many years in fact, tuberculous matter may remain embedded in the walls of an apparently healed cavity or in a mass of fibrous tissue, and though the disease is quiescent, yet at any time a fresh outbreak of the disease may occur. The patient, perhaps, need not be informed of this, for he can scarcely avoid it in any way than by the general attention to hygiene which he is bound otherwise to pay, but it should be remembered by the physician in formulating his prognosis.

I have not dealt with all the elements of prognosis, but only with those which seem to me to be of most importance. In my next lecture I will discuss with you a few points of treatment.

A Clinical Lecture

ON

THE OPERATIVE TREATMENT OF FIBROID TUMOURS OF THE UTERUS.

Delivered at the General Hospital, Birmingham, on Nov. 13th, 1900,

By EDWARD MALINS, M.D. EDIN,

OBSTETRIC OFFICER TO THE HOSPITAL, PROFESSOR OF MIDWIFERY IN THE UNIVERSITY OF BIRMINGHAM.

GENTLEMEN,—In the course of our comments upon the treatment of fibroid tumours of the uterus you have, no doubt, been struck with the considérable diversity of opinion expressed by various authorities. You will remember that some months ago the question of operative treatment was brought to our notice by some cases in the wards. I then resolved to put the next half-a-dozen cases which came under my observation to the test with a view of demonstrating to you the best plan generally to follow. I have, therefore, taken these six cases of supra-vaginal hysterectomy, not, indeed, as offering anything new, but with the object of submitting a short clinical account and arousing an interest in a class of cases which are frequent enough to warrant the statement that, like other and less desirable patients, they represent a type which is always with us.

No doubt in dealing with the question of treatment in this particular disease the greater principles include the less in discussion, but it is more especially with the operative methods that I wish to offer suggestions and to state my conviction that in the plan adopted we have in certain cases an ideal operation, one which amply satisfies the demands of the disease, and which, when favourably carried out, reflects with credit upon the surgical art of modern times—a cure effected with less reservation than is attached to many abdominal operations, a restoration fulfilling not merely the purpose of statistics or adding to the glamour of individual skill, of which, indeed, there is no monopoly, but an enduring benefit obtained by the patient and a solid satisfaction to those who minister to it. The operation is comparatively simple. I premise a preliminary preparation of the field, in which the vagina is also strictly attended to. The Trendelenburg position is a very desirable adjunct if it can be obtained: it adds greatly to the advantage of sight and facility of manipulation. The abdomen is opened in the middle line in the usual way and if possible the tumour is brought outside; if not, the first steps, at all events, can be done *in situ*. A ligature of strong silk is placed through the broad ligament near the pelvic wall and firmly tied, thus securing the ovarian vessels. A second ligature or a pair of rather long-beaked, narrow forceps is placed at the uterine end of the broad ligament, near to the cornu of the uterus; the part between them is cut through The round ligament is also tied. The process is repeated on the opposite side. The tumour is now much more moveable and the ovarian vessels are safe. The peritoneal covering just above the bladder is then separated in front by running a knife lightly across the cervix; the same is done behind, the ends meeting at the sides of the cervix. The bladder is then gently but well pushed down to separate it from the cervix; the uterine arteries can now be located. A blunt needle and silk ligature are passed below them and they are strongly tied. This may be either within the peritoneal fold or inclusive of it. Sometimes it may be more convenient to loosen the tissues containing the artery and to tie it separately in its continuity. The cervix or pedicle is now cut through from above downwards by a V-shaped incision at the front and back, forming two flaps which come readily together. It is recommended by some that the cervical canal should now be seared by actual cautery or that some strong antiseptic, such as carbolic acid or a solution of perchloride of mercury, should be applied to it. This I have never done, as I assume that the upper part of the vaginal canal and cervix are normally free from infective germs and that additional security has been afforded by the cleansing in this direction previously mentioned. The cervical flaps thus made are brought together by silk sutures, three or four in number. The peritoneum is brought over the end of the stump and attached to the corresponding structure posteriorly by Lembert's sutures of fine silk. Similarly the edges of the broad ligaments are joined all across the pelvis. Generally the stump where the ovarian vessels have been tied can be brought down to, or near, the angle at the side of the cervix and turned in under the peritoneal fold, thus covering all the wound over and forming a united line across the pelvis, which represents a neat finish to this part of the operation The pelvic cavity is then made perfectly clean and dry and the abdominal wound is closed. The latter is effected by running five or six silkworm gut sutures through the walls; these are held together on each side by a pair of forceps while the other sutures are put in. The peritoneal edges are brought together by a running catgut suture, the fascia by fine silk interrupted sutures and the skin by catgut sutures, continuous or interrupted; the silkworm gut sutures are then finally tied. But occasionally conditions are found which necessitate considerable modifications to this plan and which serve to tax our resources severely. When the tumour is intra-ligamentous growing more or less within the layers of the broad ligament and involving adjacent structures, it is impossible to eliminate it in this way. The best plan in such cases is to modify the procedure as follows. The broad ligament and the round ligament are tied on one side, whichever is the more free; the broad ligament is then cut through on the same side down to the level of the uterine artery, and this is firmly secured. The whole mass is then dragged to the opposite side and the cervix is cut across; the bladder being separated in front, the uterine artery is now found and ligatured. This assured the growth can be separated from between the layers of the broad ligament up to or near to the ovarian vessels These can be clamped or tied and the operation may be completed in the usual way. The altered relations of the ureter or inflammatory adhesions demand more caution and attention to detail Step by step the process can be accomplished, and as a rule a satisfactory ending can be obtained though more anxious and more prolonged in the performance. The cardinal points in all operations of this kind appear to stand out in relief—they are complete asepsis, perfect hæmostasis, and accurate adaptation of adjoinin parts; the peritoneum being ever kept clean and dry. Without doubt the Trendelenburg position materially lessens the difficulties; it is a factor which has conduced largely to the confidence and to the comfort of the operator, to the ease and celerity of the operation, consequently, therefore, to its success.

The indications for operation upon such cases present themselves generally in a definite form and may be received as reliable reasons for interference. I am well aware that the majority of fibroid tumours call for no active surgical interference. I have under observation a number of such patients, some of more than 20 years' standing, many of whom are content, if not satisfied, to pursue the uneven tenour of their way with placid acquiescence and belief in the powers of nature. At times their faith is shaken, they falter for the moment in their confidence, but soon drift again into the position of masterly inactivity. Fostered by semi-invalidism and with no lack of comforts they can afford to exist and even to enjoy bad health. Such a condition, in the well-to-do classes at all events, is often accepted with passiveness born of hope for the future. In the working-classes this attitude is intolerable; this expectant probation is an illusion—they must do or die; they cannot supinely wait. Hence comes an influence in our advice as to operative treatment. It must inevitably be allowed to play an important part, and, I think, may justly be considered to be an element in the pursuit of active measures. 1. Social position, therefore, becomes to some extent a guide in the selection of cases for operation. 2. Excessive and persistent hæmorrhage undoubtedly is a ground for interference—hæmorrhage which has resisted for a length of time rest, hot douches, and therapeutics of tried and of unknown efficacy. I have little confidence in these so called hæmostatics. The continued use of ergot is lauded as a standard prop by some in such cases—it is a broken reed to lean on and often fails when most trusted for help. Nothing that I know of medically admits of a safe prediction as to results in cases of this kind. We know that oftentimes the bleeding is erratic. We learn, too, that the drug last administered at a venture often gets the credit—the outcome of credulity which is met by a specious and hollow success. 3. Occasionally the pain and discomfort due to pressure symptoms entail a consideration of interference. This is most frequent when the tumour is in the pelvis, where it encroaches upon neighbouring viscera or nerves or distends the uterine walls, giving rise to suffering of a severe kind. As the tumour rises from the pelvis in its growth these symptoms often subside, and it then happens that the only symptoms arise from the weight and discomfort of the mass. The effect is a mechanical one, disarranging functions and causing inability to obtain rest for any length of time in one position or to move about with ease. Still, large tumours may exist with very little complaint on the part of the patient who by long continuance becomes accustomed to, and tolerant of, the burden. There is a mutual adaptation of the patient and the tumour to each other. 4. Rapid growth of the tumour is a first indication for the review of surgical treatment. But even here we often meet with difficulties in the formation of a decisive opinion. The ways of fibroids are dubious and inconsistent. The rate of growth is sometimes visibly fast, it may then stop without apparent cause and remain stationary for a length of time. In such circumstances it provokes a revision of our advice and an alteration in the patient's inclination to submit to a serious operation for its removal. When the rate of growth is unquestionable, and particularly if there are signs of associated complications, our path becomes more clear and our duty imperative. There is less need for conservative surgery when the functions of the uterus and ovary have fulfilled their destiny, but there is great need of help when signs of degenerative changes occur or complications threaten to gain the mastery of the patient.

But, it may be asked by some, why wait until untoward signs or symptoms appear? why not operate early in order to avoid the greater peril of a more severe operation when the growth is larger and circumstances are less favourable? These questions indicate the trend of modern surgery based upon sound judgment and the experience gained in the success of operative details. But few will pretend that because a fibroid tumour is present the patient must be operated upon. What I have already remarked shows how faulty such a practice would become. There are, however, numbers of patients to whom a life of misery would be avoided, an untimely death prevented, and restoration to usefulness achieved if a timely warning had been heeded. Nor is this picture overdrawn. The testimony of expert witnesses proves how real are the dangers which environ the subjects of fibroid growths. Martin of Berlin furnished an analysis of 205 cases of fibroid tumour which had been submitted to operation. Discussing the changes to which they are liable he states that in at least 38 out of the number, or in about 18 per cent. of the cases, changes took place in the fibroids that seriously endangered the life of the woman. The great majority of cases, says a high authority,[1] demand operative treatment. The danger of operation is much less than the danger to which the woman is exposed from the various accidents which are liable in this disease. Dr. G. E. Herman[2] quotes Dr. Matthews Duncan whose words are always entitled to respect: "A woman with an enormous fibroid will not live to be an aged woman." Writing of the degenerative changes in the tumour, changes in the heart, pressure symptoms, &c., Dr. Herman says that these are thus not merely contingent risks but actual and persistent evils. "A well-advised patient will therefore welcome relief by operation." Mr. Bland-Sutton,[3] with the enthusiasm of his skill, advocates early removal of such kind of tumours as involving less operative danger and a diminished peril to life. He performed 28 operations with two deaths. Dr. W. Duncan[4] publishes 68 cases with four deaths, and Dr. W. J. Gow stated at a meeting of the Obstetrical Society of London that in 18 months he had saved 16 out of 17 cases. The largest number of statistics is given by Dr. Herman from Olshausen. Thus in 806 cases of supra-vaginal amputation of the uterine body there were 45 deaths, or 5·6 per cent., and 520 cases of removal of the whole uterus (so-called "panhysterectomy"), with 50 deaths, or 9·6 per cent.[5] Additional evidence of success might be brought from many operators, but enough has been said to be suggestive of serious consideration in our views of operative treatment and to point to the direction in which the surgery of our time is capable of extending beneficial aid.

CASE 1.—Operation in this case was performed on June 19th, 1900. The age of the patient was 45 years. There was history of influenza some two years previously, since which the general health had failed. The body was thinner and the abdomen was steadily getting larger, with pain in the back and inability to move about with ease. The abdomen was occupied by a large, rounded, smooth, elastic tumour reaching about four inches above the umbilicus per vaginam. The cervix was high up posteriorly. The body of the uterus was not well made out, but it moved with the mass bimanually. There was a bruit at the base of the heart. There was no albumin. The catamenia varied in amount and regularity. The operation was performed in the manner which has been described. The growth, which was interstitial from the back of the fundus, weighed 10 lb. 2 oz. The ovaries were large and cystic. The highest temperature was 100° F., on the day after operation, and the highest pulse was 108, on the same day, after which the normal condition was resumed and good recovery followed, the patient leaving the hospital on July 16th.

CASE 2.—The patient, a married woman, aged 28 years, was operated upon on July 11th, 1900. Previously to her marriage, which took place in October, 1899, she had menstruated irregularly and profusely. After her marriage she noticed a "lump" in the lower abdomen which rapidly increased in size. Menstruation had become constant. There was pain in the back and difficulty in movement was complained of. A central, hard, irregular tumour was felt in the abdomen, reaching to the lower level of the umbilicus and extending to each side. A mitral bruit was marked. There was no albumin. The patient expressed a wish for operation in the face of the pain, the hæmorrhage, and the rapid growth of the tumour. This was carried out in the usual way. The growth was nodular and hard and sprang from the posterior wall of the uterus; it weighed 3 lb. 12 oz. The ovaries were large and cystic and the broad ligaments were short. Nothing eventful followed the operation and the patient went home on August 4th. She has since written to say how well she is.

CASE 3.—The patient, a pale, thin, anæmic woman, aged 39 years and unmarried, was operated upon on July 26th, 1900. A year previously she had noticed a "lump" on the left side of the abdomen and a few months ago another one on the right side. Menstruation was irregular and profuse and the patient suffered from pain and weakness. In the left iliac and hypogastric region an elastic, rounded, smooth tumour could be felt. To the right of the middle line a hard mass reached in the pouch of Douglas below, and bimanually it was felt to be incorporated with the uterus. At the time of operation the left side was found to be occupied by an ovarian cystoma, and on the right was a hard fibroid. The whole was removed with the uterus. The fibroid weighed 2 lb. 8 oz. The ovarian cyst contained 40 ounces of thin, mucoid fluid. For a few days after the operation the temperature continued at 101° F; the patient was flushed and restless, with no increase in the pulse-rate. A week later after a normal interval the temperature again rose, but subsequently the patient did well. She left the hospital on August 21st, and after a few weeks' convalescence returned to her duties.

[5] Op. cit., p. 846.

CASE 4.—In this case the operation was performed on August 7th, 1900, upon an unmarried woman, aged 44 years, who for two years previously had noticed a swelling in the abdomen. Menstruation was profuse and irregular and there were clots. Several times there had been retention of urine. In the hypogastrium a hard, rounded mass was felt which was continuous with the uterus. The cervix was pushed up posteriorly. Bimanually an irregularity of the mass was noticed. There was a systolic bruit at the base. There was no albumin. The tumour, which weighed 2 lb., sprang from the anterior and posterior walls of the fundus; posteriorly it was covered by the uterine wall, anteriorly it was sub-peritoneal. The left ovary was normal but the right was enlarged and cystic. There were numerous small, broad ligament cysts. The highest temperature reached was 100 4° F. and the highest pulse-rate was 88. The patient left the hospital on August 30th in a good condition.

CASE 5.—The patient, who was 51 years of age, had been married for 13 years but had had no children and there had been no miscarriages. 18 months previously she had noticed that her abdomen was getting larger and that recently it had been increasing in size more rapidly. Menstruation was fairly regular but profuse. She had been getting thinner generally and had suffered from pain and discomfort after food and on movement. The heart sounds were normal and there was no albumin. The abdomen was occupied by a firm hard mass reaching above the umbilicus; its circumference measured 39 inches. From the umbilicus to the right spine it measured eight inches and to the left spine seven inches. Per vaginam the cervix could be felt high up in front with a hard mass behind, continuous with the growth above. The patient was anxious for operation. This was done on Sept 12th, 1900, in the same way as in the previous cases. The tumour was dumb-bell shaped, the lower hard mass filling the space of Douglas, the larger growing from the fundus. Its weight was 5 lb. 8 oz. There were some spaces with reddish-coloured thin fluid inside. The recovery was rapid and the patient returned home to the country on Sept. 29th.

CASE 6.—The operation in this case was performed on Sept. 27th, 1900. The patient, who was 33 years of age, was married on August 29th. Some weeks before there had been retention of urine. Since the time of her marriage the abdomen had been getting rapidly larger. Menstruation was profuse and painful, and the general health of the patient had been failing. There were a hard mitral bruit, sickness, and anæmia. A mass was felt in the abdomen reaching obliquely across from above the umbilicus on the left to behind the uterus below and bulging into the right iliac fossa on its way. The cervix was high up above the symphysis. The patient was advised to go to the seaside to improve her general health before any operation. This she did with much benefit. The operation revealed a large fibroid mass, nodular and hard, growing from the fundus; it weighed 4 lb. 3 oz. The ovaries did not show any change. The recovery was not marked by any incident worthy of notice. The patient returned home on Oct. 20th and has continued to improve in health and appearance.

Vaginal hysterectomy.—You have opportunities, not infrequently of seeing this operation. In the time at my disposal now I do not intend to carry you into the details of the operation which you must see and judge for yourselves. It is applicable to the smaller cases of tumour, which are, as a rule, accessible from this aspect. Not that it is confined to these only, for some operators prefer this route and extract tumours by it which reach to the level of the umbilicus.[6] In this operation I usually tie the broad ligament on each side instead of using clamp forceps. Occasionally it will be seen that the uterus has to be divided anteriorly in order to deal with adhesions or after difficulties in extraction. It is the exception to find that patients so operated upon go wrong; as a rule the cases give rise to very little anxiety and are singularly free from rise of temperature or pulse. When by splitting of the uterus the complications cannot be overcome there is yet another plan to fall back upon—morcellation—that is, cutting away piece by piece of the uterus until it is all, or sufficient, taken away to make a satisfactory termination. This is tedious and troublesome, but it repays the time and the attention given to it when ablation cannot be otherwise attained

THE BOWEL LESION OF TYPHOID FEVER.

BY T. J. MACLAGAN, M.D.

THE cause of typhoid fever, the true nature of the poison which gives rise to it, was long obscure. We now know that it is a minute organism, the typhoid bacillus, first described and figured by Eberth in 1880. It is a short thick bacillus with rounded ends, which is largely reproduced in the system during the course of the disease to which it gives rise and is found abundantly in the glands which suffer during an attack of typhoid fever. This bacillus is directly or indirectly the cause of all the phenomena of that disease—the bowel lesion among others. That lesion is indeed the most prominent and important result of the action of this poison, constituting as it does the characteristic and essential feature of the disease to which it gives rise. How does the bacillus cause this lesion?

An organism which grows in, and at the expense of, another is a parasite. A distinctive feature of parasitic organisms is that each has its own nidus, its own special habitat, in which it flourishes and is reproduced, and in which its vital activity and morbific effects are chiefly manifested. The parasite of ringworm attacks the roots of the hair of the scalp; that of sycosis the roots of the hair of the moustache and beard; the trichina spiralis finds its home in muscle; hydatids have a special affection for the liver; and so through the whole parasitic world each parasite has its own special organ or tissue in which it is reproduced and which is the chief seat of its action as a disease-producing agency.

What applies to the grosser parasites applies equally to the very minute ones which constitute the poisons of specific diseases. The tubercle bacillus specially affects the lungs and glands of susceptible subjects; the poison of erysipelas attacks the skin, that of pneumonia the lungs. So with the poisons of the specific fevers: that of scarlet fever finds its nidus in the skin and throat; it is in these localities that it is specially reproduced and its specific action manifested, and it is in the discharges from the throat and in the peeling cuticle that the poison, therefore, most abounds. The poison of small-pox has its nidus in the deeper layer of the skin and exists in greatest abundance in the pustules which form there; it is, indeed, the very rapid reproduction of the poison in that locality which causes the disturbance which results in the formation of the pustules. The typhoid poison finds its nidus in a particular set of glands in the small intestine; it is there that its action is specially manifested, and it is in the affected glands and in the discharges which come from them that the poison exists in greater abundance.

What imparts to each of the specific fevers its distinctive and characteristic feature is not any peculiarity of the general febrile disturbance but the existence of a special local lesion. The seat of this local lesion is the nidus of the parasite: in scarlet fever the skin and throat; in measles the skin and mucous membrane of the respiratory tract; in small-pox the deep layer of the skin; and in typhoid fever the intestinal glands. The action which takes place in this nidus is the vivification of this poison, an action which in its results is analogous to the fecundation of non-parasitic organisms. It is the first act in the play, the first incident in the series of events which make up the history and course of an attack of any of the specific fevers.[1]

---

[1] *The only one of the specific fevers* which has no local lesion is relapsing fever: it is also the only one in which the special poison of the disease (the spirillum) is found largely in the blood. It has no local lesion because the blood is the special nidus of its parasite.

It is from this point of view, from the point of view of the essentially parasitic nature of the typhoid poison, that we have to approach the subject of its mode of action and of the nature and mode of production of the bowel lesion of typhoid fever. That the typhoid poison causes that lesion and that the lesion is peculiar to, and distinctive of, typhoid fever are two established pathological facts.

There are two sets of glands in the intestine—those situated in its mucous lining and those which have their seat in the submucous coat. In the mucous lining are found the glands of Lieberkühn, distributed all over the bowel, but more abundant in the large than in the small intestine. They are small tubes closed at their deeper extremity. In the submucous coat are found (*a*) Brunner's glands which have their seat in the submucous coat of the duodenum and consist of minute lobules with branching ducts which open on the mucous surface of the bowel; (*b*) solitary glands or lymph follicles, consisting of small round or oval masses of adenoid tissue which are scattered more or less all over the bowel; and (*c*) the agminated glands or Peyer's patches, which consist of masses of lymph follicles grouped together in the submucous coat. They are found in the jejunum and ileum, chiefly in the ileum, and most abundantly at its lower part, near the ileo-colic valve. These patches vary in length from half an inch to one and a half inches; they are oblong in shape, their long axis being that of the bowel. They are largest and most closely packed at the lower end of the ileum. These are the glands that specially suffer in typhoid fever. The solitary glands are also affected to an extent which corresponds to their small size and more sparse distribution. Brunner's glands do not suffer. The brunt of the disease is borne by the Peyer's patches. These glands are not equally developed at all periods of life. In infancy they are small and not easily detected; as years go on they become larger, and by the time that the age of 15 years is reached they are prominent objects in the intestinal wall and remain so till middle life. They then begin to get smaller and gradually dwindle away till in old age they disappear. Their period of greatest activity is from 15 to 35 years of age; it corresponds exactly to the period of greatest susceptibility to the action of the typhoid poison. The immunity from typhoid fever enjoyed by the very young and the very old finds its explanation in the life-history of these glands. They scarcely exist in the infant and they dwindle away in old age. The typhoid bacillus may enter the systems of such subjects and circulate in their blood, but it finds no nidus, no soil in which it can be vivified and reproduced; it is, therefore, without action on them. For it is in these glands, and in these glands only, that the typhoid poison finds the material necessary to its vivification and reproduction; it is in them that it commences its course as a disease-producing agency; it is in them that its morbific effects are most pronounced; and it is the destructive action which takes place in and around these glands that gives rise to the most formidable and fatal complications of typhoid fever.

How is this effect brought about? What is the mode of action of the typhoid poison on these glands? and what is the mode of production of the lesions which are found in the post-mortem room? Let us trace the course of events in one gland from beginning to end, for what takes place in one gland is what takes place in all, the whole bowel lesion being but the sum total of the lesions of the individual glands. A typhoid germ having entered the circulation may or may not reach one of these glands, may make the round of the circulation again and again, and may ultimately pass out of the system by one or other of the eliminating channels without ever coming in contact with its nidus, and therefore without doing any harm. That is possible; and probably such an event is of not infrequent occurrence, especially in infants and old people; but we are now dealing with a case in which the poison does come in contact with, and enter, one of the glands which constitute its nidus. A bacillus can enter only one gland; this may be a solitary gland or it may be one of Peyer's patches. The chances are very much in favour of its being one of these patches at the lower end of the ileum, and that simply because by the ordinary doctrine of chance the germ, no matter whether it enters the system through the lungs or by way of the stomach, is more likely to be brought in contact with one of these numerous patches than with a small solitary and isolated follicle. The germ then enters one of these patches; but it cannot at once affect the whole gland; it enters only one of the numerous follicles of which the gland is composed; it is there reproduced, giving rise, say, to four others (though it may with equal probability be ten or a dozen); these four soon have 16 descendants; these 16 have 64, which in turn act like their parents, and so the process goes on, the germs ever increasing in number, and doing so with ever-increasing rapidity as they become more numerous; they escape into the circulation, pervade the system, grow in the tissues, and invade other glands in the bowel. Meantime the morbid process advances in the one first attacked—follicle after follicle is rapidly affected till the whole gland is invaded. This rapid increase of the typhoid poison within its structure necessarily causes increased vascular activity and increased flow of blood to, and corresponding excitement in, the gland. For the bacillus, in virtue of its nature, takes from the blood the same materials which the tissues of the gland take up. The excitement thus produced in the gland results in proliferation of its cellular elements and consequent increased size and thickening of the gland, which thus becomes a prominent object in the intestinal wall. This marks the completion of what may be regarded as the first stage of the bowel lesion. The gland is inflamed, swollen, hard, and a prominent object in the intestinal wall, but still entire and unbroken. In a certain number of cases the lesion goes no further, the inflammation terminates in resolution, the swelling subsides, the gland returns to its normal condition, and the disease comes to an end by the middle or end of the second week. It is only in a minority that this favourable result takes place. In most cases the morbid process continues and the inflammation increases till the gland softens, dies, breaks down, and sloughs away. This it does during the third week. By the beginning of the fourth week the sloughing process is generally completed and there is left behind a clean sore which soon begins to heal. This terminates the second and, in favourable cases, the final stage of the disease.

That is the normal course of events in a Peyer's patch in an ordinary typical case of typhoid fever in which convalescence begins at the end of the third or beginning of the fourth week. But though the story of one gland is the story of all, the general picture of the events and incidents which make up the complete history of the bowel lesion is not quite so simple, and that mainly because the individual lesions which constitute the sum total of the bowel troubles are not quite contemporaneous, and, therefore, not equally far advanced at any given time. The glands are not all attacked at the same time. One always suffers first, then others follow at varying intervals. The morbid process is thus not equally advanced in all. In those first attacked the destructive process has reached its height and they begin to soften and break down, while others are still only in the stage of thickening and enlargement. As a result of this we constantly find in the same bowel, especially in cases which prove fatal during the third week, two sets of lesions, the hard and the soft, the *plaques dures* and the *plaques molles* of Louis. They are exactly the same lesion at different stages of development. The hard would have broken down and become soft had the patient lived a little longer. Louis thought that the *plaques molles* were more common than the *plaques dures*, and in the post-mortem room no doubt they are so, for most, and in many cases all, of the glands slough, break down, and become soft before death takes place. Whether or not, therefore, *plaques dures* are found after death depends on whether or not there has been time for the most recently affected glands to soften and break down before the fatal termination. They are more likely to be found in cases which prove fatal during the third week than in those which run on into the fourth or fifth. All the soft lesions were hard before they became soft, and all the hard will become soft if time is given them to do so, unless, indeed, they terminate in resolution.

The morbid process is most pronounced at the lower end of the ileum near the ileo-colic valve. From this it has

---

That poison finds in the blood what the poison of small-pox finds in the skin and the poison of typhoid fever finds in the intestinal glands—that something which a nidus supplies to the parasite and which is essential to its vital activity. In this respect, in its peculiarity of finding its nidus in the blood, the spirillum of relapsing fever resembles the plasmodium malariæ, and the disease to which it gives rise is stamped with some of the characteristics of intermittent fever. It is indeed a sort of clinical link between the continued and intermittent fevers; it is highly contagious and occurs in widespread epidemics; it therefore takes rank among the contagious fevers, but it has a relapsing or intermitting course, it has no local lesion, one attack confers no immunity from a second, and the poison is found abundantly in the blood. In these respects it resembles malarial fever.

been supposed that the lesion commences there and spreads upwards. The reason why the lower end of the ileum suffers most is that the glands which are specially affected in typhoid fever are most abundant and most closely packed at that end. The typhoid bacillus finds the material necessary to its growth and propagation in greatest abundance there; it is this concentration of the susceptible glands and consequent richness of the soil that makes the morbific action of the bacillus so pronounced in that locality. The discharge from one gland may, and probably often does, irritate neighbouring glands, but the ones to suffer in this way will be those below, not those above, the discharging gland, for the trend of the bowel contents is downwards, not upwards; and probably one reason why the lesion increases in severity as we descend the ileum is that the discharges from all the upper affected glands must pass over those below them; the lower we descend the greater the disturbance from this cause.

Yet another agency comes into operation here: the swelling and turgescence of the mucous membrane at the ileo-colic outlet so narrows that opening that the passage is likely to be less free than usual, causing some retention in the ileum of its irritating contents. These are adjuvant causes, but, after all, the primary reason why the typhoid lesion is most marked at the lower end of the ileum is that the Peyer's patches are largest and most numerous in that locality; they are so abundant that there is little room for healthy bowel between the lesions.

The state of the glands and the changes which take place in them as a result of the action of the typhoid poison have been described by many pathologists. The best of the early accounts is that given by John Goodsir who describes the morbid changes as consisting in "the development of cells within the constituent vesicles of the patches to such an extent as at last to burst them or cause their solution, the continued increase in the number of cells proceeding from as many centres as there are vesicles in the patch, the conglomeration of the whole into one mass above the submucous and under the mucous membrane, the distension of the latter and the necessary ulceration and sloughing of the mass arising from the circumstance"[2] All descriptions of the lesion agree with Goodsir's. They all describe it as essentially consisting in swelling and thickening of the glands due to proliferation of their cellular elements. Malory, the most recent observer, describes and figures this increased development of cells, which he says "may take place diffusely through the lymph nodule, but may also start at the centre or at the periphery."[3] The change which takes place in the affected glands is an acute proliferation of their cellular elements and cellular and granular contents and consequent swelling of the follicles. This must be caused by acute irritation arising within the substance of the patch, for there is no appearance of external irritation or disturbance and no increased vascularity of the mucous surface till the follicular changes are well advanced. The cause of the whole disturbance is the rapid reproduction of the typhoid bacillus within the substance of the follicles.

It has been supposed by some that the phenomena of typhoid fever, including the bowel lesion, are caused, not directly by the typhoid bacillus, but by a toxin produced by the bacillus in the blood. Such a poison would in virtue of its nature be equally diffused through the blood and would necessarily affect all the glands equally and at the same time. But it is matter of demonstration that the intestinal glands are not all affected at the same time. In the same bowel there are constantly seen lesions at various stages of development, some only at the stage of hardening and swelling, while others have gone on to the stage of softening and sloughing; and some glands escape altogether, as is evidenced by what is observed in cases of fatal relapse; there the lesions of the first attack are seen to be clean and healing, if not quite healed up, while those of the relapse are still in the sloughing stage. Only on the view that the poison is particulate and not equally diffused through the blood can this be explained, for were it equally diffused and a toxin the cause of the disturbance all the susceptible glands would suffer, they would all be affected at once, at the time of death the morbid process would be equally advanced in all, and relapses with fresh lesions would be impossible.

This toxin hypothesis is not only cumbersome and unnecessary but is also less satisfactory than that which attributes the essential phenomena of typhoid fever to the direct action of the bacillus. There is no evidence of the existence of a typhoid toxin and no adequate reason for postulating its existence. There is ample evidence of the existence of the typhoid bacillus; it is a common acquaintance, we know it by sight, we recognise it as the cause of typhoid fever and do not for a moment question its claim to be so. Why go in search of a problematical cause when we have to our hand one which we know to be in active existence and whose action gives an adequate and reasonable explanation of the phenomena with which we are dealing?

But though I regard the view which ascribes the essential phenomena of typhoid fever to the action of a toxin as untenable, and look upon the bacillus as competent to produce them all by its direct personal action, though I claim this important rôle for the bacillus, and believe that it is directly by its action that the essential phenomena of typhoid fever are caused, I by no means exclude from consideration the possibility of other morbid agencies coming into play. On the contrary, I believe that after the glandular lesion has reached the sloughing stage other agencies do come into play, and that to these agencies are to be ascribed many of the more serious symptoms which are apt to show themselves in the third and fourth weeks of the illness. For with the process of sloughing and suppuration there come into play other morbid agencies—agencies which not only prolong the illness but add much to its gravity. These agencies are the various forms of cocci (streptococci, staphylococci) which are associated with the processes of sloughing and suppuration. It is at this stage that toxins might not unreasonably be supposed to come into play, the toxins, not of the typhoid bacillus, but of the cocci which accompany the suppurating stage of the bowel lesion. This stage of typhoid fever resembles both clinically and pathologically the stage of secondary or suppurating fever of small-pox, which shows itself on the eleventh or twelfth day of that disease when the variolous eruption enters on the stage of suppuration, this secondary fever being caused not by the small-pox bacillus, but by the organisms associated with the process of suppuration.

Had we nothing to deal with in typhoid fever but those symptoms and lesions which are the direct and necessary result of the action of the typhoid bacillus, were the general symptoms of the disease only those caused by this bacillus, and were the bowel lesion limited to such disturbance as essentially results from its direct action, it is probable that all cases would terminate at the end of the second stage, that typhoid fever would be bereft of most of its dangers, and that the percentage of deaths from it would be very much smaller than it is. The typhoid bacillus acts solely on the glands of the submucous coat On the mucous, the muscular, and the peritoneal coats it has no direct action; and yet it is to lesions involving one or more of these coats that the most serious and formidable complications of typhoid fever are due. In the early stages of the disease there are swelling and hardening of the glands, but no inflammation or unusual redness of the mucous membrane. Not till the glandular lesion is well advanced and has entered on the sloughing stage does the mucous membrane give evidence of being seriously involved in the morbid process. It is not the typhoid bacillus but the irritating discharge from the gangrenous and sloughing glands that causes the redness and turgidity of the mucous membrane noted in the post mortem room, and the diarrhœa which is symptomatic of it during life

So with the muscular coat; when it is invaded, as it often is, the destructive effects produced are caused not by the typhoid bacillus but by the irritating discharges which come from the sloughing gland lying on its surface. In their destructive course these discharges may penetrate the muscular coat and invade and even penetrate the peritoneal lining of the bowel. In the production of the bowel lesion of typhoid fever there are thus two agencies at work: (1) the typhoid bacillus; and (2) the irritating discharges of the sloughing glands. The former operates during the whole course of the disease; the latter comes into play towards the end of the second week; and not till it comes into action are serious symptoms apt to show themselves, for it is not till this sloughing process affects the mucous lining of the bowel that diarrhœa is apt to occur; it is not unless and until the muscular coat with its free blood-supply and larger vessels is invaded that serious hæmorrhage occurs; and it is not until by the continued destructive action of this process the muscular coat is penetrated and the peritoneum invaded that we have evidence of peritoneal inflammation with its attendant dangers.

---

[2] London and Edinburgh Monthly Journal of Medical Science, 1842.
[3] Journal of Experimental Medicine, New York, November, 1898.

For clinical purposes cases of typhoid fever may be divided into three classes: (1) those in which the glandular lesion does not pass beyond the stage of inflammatory thickening but terminates in resolution without sloughing, and in which convalescence commences at the middle or end of the second week of the fever; (2) those in which the lesion terminates in sloughing of the glands but in which the process is limited to the glands and the mucous membrane immediately over them, and is accompanied by no evidence of active disturbance and no serious indications of bowel irritation, and in which convalescence usually begins at the end of the third week; and (3) those in which the sloughing process is more extensive and in whose course diarrhœa, hæmorrhage, abdominal distension, peritonitis, with attendant typhoid general symptoms show themselves during the third and fourth weeks of the disease and in which life is seriously threatened by these complications. The fact that it is only a minority of cases of typhoid fever that come under this third class, and only in a minority, therefore, that the serious symptoms which characterise it occur, show that these symptoms are no essential part of the typhoid process, no essential part of the action of the typhoid bacillus on the bowel. And a very little consideration will show why there should be so great a variety in the severity of the bowel lesion in different cases. For what is the state of matters? Up to a certain point the local lesion consists only in inflammation of some glands situate in the submucous coat of the bowel—from a clinical point of view the least important of all its coats. So far as any local effects are concerned the lesion, while still only in the inflammatory state and limited to these glands, is a comparatively trivial one, so trivial that it causes no disturbance, no local symptoms of any kind, and gives rise to no trouble by which its existence could be diagnosed. We know that the lesion is there only from what we know of the natural history of the disease, for at that stage it has no clinical symptoms.

The advent of the stage of sloughing alters the whole aspect of affairs, for then we have to deal, not with simple inflammation, but with gangrene and all its attendant dangers. These dangers may or may not declare themselves, but they are always there and often do come very much to the front. Hitherto the lesion has been limited to the unimportant submucous coat and has consisted in proliferation of the cellular and granular contents of the affected glands, but now, when sloughing sets in, we have to deal with a more or less virulent destructive process which spreads to other coats; affecting the mucous coat it causes turgidity, redness, inflammation, and destructive ulceration; spreading to the muscular coat with its free blood-supply it exposes the sufferer to all the risks of serious hæmorrhage and to the still greater risks attendant on extension of the mischief to the peritoneal coat. But even that is not all. The dangers attendant on gangrene are not only its local destructive action on the affected textures; there is also the very great danger of septic poisoning, a danger which is specially marked when the structure involved is so rich in lacteals and in veins as that which suffers in typhoid fever. What we have to deal with after the second week in bad cases of typhoid fever is not only the symptoms, local and general, caused by the typhoid bacillus, but those due to the absorption into the system of septic material derived from the sloughing and gangrenous sores—sores which are situate in a mesh of veins and lacteals whose function it is to absorb and carry things into the system. That, more than the direct action of the typhoid bacillus, is the cause of those alarming symptoms, general as well as local, which characterise the late stages of bad cases of typhoid fever. The local symptoms are those of gangrenous ulceration of the bowel; the general symptoms are those of septic poisoning.

From this pathological standpoint we may now survey the symptoms to which the bowel lesion gives rise during life and weigh the clinical importance of each.

Diarrhœa.—This is not an essential feature of typhoid fever; many cases run their course from beginning to end without its occurrence, while in not a few the bowels are constipated during the whole course of the malady. These are generally mild cases in which the bowel lesion is not sufficiently severe to give rise to any symptoms, and in which we know that it exists only from what we know of the natural history of the disease. Mere inflammatory swelling of glands situate in the submucous coat, without any participation of the mucous lining in the mischief (and that is what we have to deal with during the first week of the disease), is not likely to cause diarrhœa or any other local symptom. It is not till the glands begin to slough and break down and the mucous membrane over them becomes involved in the morbid process that diarrhœa is apt to occur. Such diarrhœa is symptomatic, not of inflammation of the glands of the submucous coat, but of the extension of the ulcerative process to the mucous membrane. In fatal cases in which diarrhœa has been a marked symptom during life the turgid redness of the mucous membrane around and between the ulcers gives ample post-mortem evidence of the extent to which that membrane had suffered during life.

The amount of diarrhœa varies much. There may be only two or three loose stools in 24 hours or there may be 10 or 12. Their frequency depends on the extent and severity of the local lesion. Up to a certain point looseness of the bowels is rather favourable than otherwise; beyond a certain point it becomes unfavourable. It is obviously desirable that the separated sloughs should be got rid of and not be allowed to lodge about in the bowel, irritating it and tending to poison the system. Two or even three free stools a day favour the discharge from the bowels of their sloughy and injurious contents; by so doing they more than counterbalance any weakness resulting from their occurrence. More than three such stools a day is more than is desirable, and anything beyond that should, if possible, be checked. Persistent and frequent diarrhœa occurs only in severe cases and is always an unfavourable symptom. It means that the bowel lesion is very extensive and that there is much ulcerative destruction and inflammation of the mucous as well as of the submucous coat. The stools in typhoid fever are generally pale in colour. In milder cases they are of the colour and consistence of pea-soup; when diarrhœa is more marked they are thinner and more like ochre. In very severe cases they may be dark in colour from oozing of blood from the ulcerated surfaces. The occurrence of frequent dark-coloured stools is one of the gravest complications of typhoid fever. The stools are always more or less offensive and have an alkaline reaction.

Hæmorrhage.—Bleeding from the bowel is generally regarded as one of the gravest complications of typhoid fever, and yet we find such distinguished observers as Trousseau and Graves and Griesinger recording the opinion that such hæmorrhage may be innocuous and in some cases even beneficial. The importance to be attached to it, its attendant danger, and its prognostic significance depend on its amount and on the period of the disease at which it occurs. The intestinal arteries enter the bowel at its mesenteric attachment and subdivide in the muscular coat, sending good-sized vessels to ramify between the longitudinal and the transverse fibres; passing to the submucous coat they enter it after further subdivision and diminution in size, and ultimately reach the mucous coat much diminished in calibre. Hæmorrhage may take place from the vessels of any of these coats. From the mucous coat it may take place in one of two ways: it may be due to rupture of distended and engorged veins or it may take place in the ordinary course of ulceration. When due to rupture of veins it occurs early in the case, is not of great amount, and is not unlikely to do good by relieving congestion. When it occurs in the course of the ulcerative process it is of arterial origin and occurs later. It can do no good, but neither, as a rule, does it do much harm, as the vessels of the mucous membrane are not large enough to be a source of serious bleeding. From the submucous coat blood can flow only during the process of ulceration. Such hæmorrhage can never be salutary, but neither is it likely to be very injurious, for the same reason as applies in the case of the mucous coat, the vessels are not large enough for free hæmorrhage.

Bleeding from the vessels of the muscular coat is always serious. It never takes place at an early stage of the disease, because it cannot occur till after the gland has sloughed and the irritating discharges from it begin to eat their way into the muscular coat. When once this coat is invaded there is always the risk of serious hæmorrhage. The affected glands are situated at the side of the bowels by which the vessels enter it—its mesenteric attachment. They are right over the larger vessels of the muscular coat, and should one of these be opened in the progress of the ulcer there is likely to be a considerable loss of blood. The risk of this accident is directly as the number of glands affected; it is, therefore, more likely to occur in severe cases in which many glands suffer than in mild ones in which the special lesions are less numerous. It must be borne in mind, however, that one ulcer may suffice for the purpose and that a profuse hæmorrhage may suddenly impart an aspect of gravity to a case which up to the time of its occurrence had been looked upon as quite mild. This is one of the possible accidents which make a guarded prognosis advisable in all cases of typhoid fever.

The amount of blood lost varies. It may be so profuse as to precipitate a fatal termination. It always does harm and materially affects our prognosis. It indicates the existence of at least one progressive ulcer, and there is no saying where such an ulcer may stop; it may open into other vessels or it may invade the peritoneum in its destructive course. The occurrence of profuse hæmorrhage has sometimes been diagnosed before any blood has passed per anum, pallor and prostration, failing pulse, and fall of temperature pointing to what is soon verified by the presence of blood in the stools. Cases, too, are recorded in which death took place before any blood was passed but in which it was found post mortem in the gut.

There is another form of hæmorrhage whose occurrence, though the actual loss of blood is not so great as in that which we have been considering, imparts even greater gravity to the case and more seriously affects our prognosis. I refer to those alarming cases in which during the third week or later the patient passes frequent dark-coloured, offensive stools. The dark colour is due to the intermingling with the stools of blood which comes not from the giving way of an artery but from a general oozing from the ulcerated surface. These malignant cases bear to typhoid fever the same relation that hæmorrhagic small-pox does to ordinary variola. They nearly all prove fatal.

Peritonitis.—This is an almost necessarily fatal complication in typhoid fever. It is so because of the cause which gives rise to it. In an odd exceptional case it may be caused by a splenic infarctus or rupture of a softened mesenteric gland, but in the vast majority of cases it is due to perforation of the bowel. The destructive ulcerative process which invades the muscular coat may also completely penetrate it and eat its way through the peritoneal lining as well. Peritonitis means perforation. There may be only one perforation or there may be several. Generally there is only one, and it is quite enough for all lethal purposes. The opening may be not much larger than a pin-point or it may be large enough to admit the point of the finger. The symptoms are the sudden onset of acute pain in the abdomen, increased abdominal distension, cessation of abdominal movement in respiration, pinched aspect of the face, feeble, thready pulse, and all the symptoms of collapse from which there is no rally. In the production of this accident the typhoid bacillus plays no direct part. Indirectly it is, no doubt, the remote cause of this as of all other phenomena which occur in the course of the disease to which it gives rise. But its direct action is limited to the glands of the submucous coat. The immediate cause of the destructive ulceration of the muscular and peritoneal coats, and therefore of perforation, is the irritating discharge from the sloughing glands. When the affected glands have sloughed and separated the action of the typhoid bacillus on them is at an end. *Not so that of the irritating discharge* which accompanies the processes of sloughing and suppuration. This new destructive agency comes into play as the typhoid bacillus is retiring from the field and continues its destructive action *independently of* it and on whatever *structure* it comes in contact with. It may all be carried away with the sloughs as soon as they separate and so do no great harm; or it may, from tardy separation of the sloughs or unusual severity of the attack, be retained at the seat of the lesion long enough to enable it to eat into, and even penetrate, the muscular and peritoneal coats. An agency which much increases the danger from this cause is the swollen condition of the ileo cæcal outlet. By such swelling this outlet is materially diminished in size, the passage downwards of the contents of the small bowel is correspondingly retarded, the sloughs and irritating discharges from the ulcerated surfaces are unduly retained in contact with these surfaces, with the certain risk of causing them to eat more deeply into the bowel. The more numerous the glandular lesions and the more severe the attack the greater is the chance of perforation. But here, as in the case of severe hæmorrhage, it is to be noted that one ulcer may suffice and that perforation may suddenly come like a bolt from the blue in a case whose symptoms up to the moment of its occurrence were of the mildest character.

The points to be noted in connexion with the bowel lesion are:—1. That the structures on which the typhoid bacillus exercises its specific effects are the solitary and agminated glands situated in the submucous *coat of the small intestine*. 2. That the change which it causes in these glands is inflammatory in nature and essentially consists in proliferation of their cellular and granular contents, with consequent swelling and hardening of the glands. 3. That this inflammation is generally sufficiently severe to cause gangrene and sloughing of the affected glands. 4. That the direct action of the typhoid bacillus is limited to the glands of the submucous coat; and that it has *no direct action on the* mucous, muscular, or peritoneal coats. 5. That the sloughing process which destroys the glands necessarily also destroys the mucous membrane situated over them. 6. That with the process of sloughing and suppuration there come into play other and new morbid agencies, the various forms of cocci associated with these processes. 7. That to these new agencies rather than to the typhoid bacillus are to be attributed all the more serious complications and all the formidable symptoms, general as well as local, which are apt to show themselves during the third and fourth weeks of the disease.

Cadogan-place, S.W.

CONCERNING CERTAIN APPARENTLY INJURIOUS CONSTITUENTS OF POTABLE SPIRITS.

BY SIR LAUDER BRUNTON, M.D., F.R.S.,
PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL;
AND
F. W. TUNNICLIFFE, M.D.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON.

PRELIMINARY COMMUNICATION.

THE phenomena exhibited by the human subject when poisoned by the ordinary potable spirits are very varied, and are caused no doubt by complex conditions which may, however, be divided into two classes—viz., those that depend upon the individual and those that depend upon the composition and nature of the spirit drunk. It is to the latter that we have directed our attention. These differences in the phenomena produced by the alcoholic beverages ordinarily consumed are more marked in the initial stages of alcoholic poisoning. To put it in plain language, it is when a man begins to get drunk and when he begins to get sober that he is apt to find out the quality of the liquor which he has taken. In the intermediate stage between these *two conditions*—viz., that of deep drunkenness—it matters but little. As the ethylic alcohol is common to all potable spirits, changes other than quantitative in this substance cannot be the cause of what may perhaps best be termed the subsidiary effects (*Nebenwirkungen*) of acute or chronic alcoholism. The main points in which potable spirits differ *inter se* are with regard to their aldehyde, compound ether, higher alcohol (fusel oil), and certain volatile base contents. This communication is devoted to the question of the aldehyde contents of various potable spirits and liqueurs, and especially to one particular aldehyde—viz., *furfural*.

The source of furfural in the manufacture of whisky, and of beer to a less extent, is a class of substances known as pentosanes; these are present in, and derived from, the cellulose of the grain husks. Under the influence of heat in the presence of acids furfural is formed from them. The substances which we have examined in this connexion are whisky fresh from the pot still and mature, brandy, *gin*, rum, various impure and cheap spirits used in the colonies—such, for instance, as "Cape smoke"—and also a number of Spanish, Portuguese, Chinese, and Japanese cheap alcoholic drinks. These *substances* all contain aldehydes and furfural in varying proportions, the latter substance in some cases (according to quantitative estimations made by Professor Hewitt) to the extent of 0·03 gramme per litre. The *presence of* furfural in, for instance, whisky can be easily demonstrated by taking a teaspoonful of whisky in a test tube, diluting with an equal volume of water, and adding a few drops of a sodium carbonate solution, and then a few drops of solution of aniline acetate. If the test tube be shaken up and allowed to stand a rose-pink colour will soon develop if furfural be present, and the deepness of the colour will be approximately proportional to the amount of this substance in the sample of whisky under experiment.

The experimental part of our work may be divided into two parts. We first endeavoured to ascertain the physiological action of furfural upon animals and man. In this connexion we made experiments upon cats, dogs, and rabbits and observations upon two men. By means of these experiments we found that doses of furfural of from 0·1 to 0 05 gramme injected subcutaneously caused paralysis of the voluntary muscles, and later clonic and tonic convulsions, probably due to asphyxia, with rapid and irregular breathing. An odd point about these symptoms was their transient nature; immediately after the injection of the drug the animal would fall down completely paralysed, its tongue and lips would become bluish, and its breathing sometimes very slow and convulsive and at other times irregular and rapid; it would then pass into a stage of clonic and tonic convulsions, in many cases it would vomit, and, finally, would begin to recover, being at first dazed, but rapidly becoming apparently normal. The whole cycle of symptoms would often be completed in from 20 minutes to half an hour. Sensation never seemed to be affected, the conjunctival reflex was always to be obtained, and when the voluntary muscles were paralysed strong reflex irritation (faradaic current) was generally responded to by changes in the respiratory rhythm. Smaller doses always caused symptoms of transient irritation, such as ataxia, tremors, and twitching, especially of the facial muscles. In the case of larger doses than 0 5 gramme death was produced from asphyxia due to paralysis of the respiratory muscles. Almost identical symptoms were produced when the substance was given by the stomach mixed with milk or water, in doses of about 0·5 gramme in cats. The effect of the drug was less marked when given with milk and much more marked when administered upon an empty stomach. In the case of man 0·1 gramme of furfural was taken two hours after lunch by two men; the pulse and respiration were unaltered, but about half an hour afterwards pain (like neuralgia) was felt at the back of the neck and extending up to the occipital region, and a sensation of throbbing and pulsation in the vessels of the head. A dull headache ensued which in one case lasted for the rest of the day. Both in the case of man and in the cases of animals the urine gave a furfural reaction with aniline acetate after the administration of the drug.

The second series of experiments which we undertook were made to ascertain whether the removal of the furfural, or to speak more accurately the aldehydes from the potable spirits, produced any change in the symptoms of alcoholic poisoning. One of the differences, *inter alia*, between raw and matured spirit is the quantity of aldehydes which they contain, matured spirit containing a smaller quantity than is contained in the raw spirit. Up to the present the obtaining of an aldehyde-free spirit has been a matter of some difficulty; we were, however, able by the use of a method described fully elsewhere by Professor Hewitt to remove entirely the aldehydes from any given spirit.

The symptoms of alcoholic poisoning produced by equal doses of the spirit free from aldehydes and the spirit containing aldehydes were compared in the case of animals. The method adopted was to render an animal paralytic and anæsthetic with the potable spirit under observation before and after the removal of the aldehydes and to watch its recovery—i.e., its return to what was presumably its normal state. Speaking generally it was found that the return from what may be termed profound drunkenness in the cases of animals was more sudden and was accompanied by less secondary symptoms when aldehyde-free spirit had been given. In the case of the spirit containing aldehydes the animal during the transition stage was restless, wandering from one part of the laboratory to another, and seemed, generally speaking, remarkably uncomfortable. Even when the gross symptoms of alcoholic poisoning had passed off the animal did not behave normally for some time, refusing the food offered to it, and showing marked signs of bad temper. These secondary phenomena were entirely absent in the case of the aldehyde-free spirit. The animal woke up and attempted to stand; if it could not, it went off to sleep again. When it was sober it appeared perfectly normal and if offered food took it

The interest of these observations lies in the fact that these disagreeable symptoms, which seem analogous to those occurring in the human subject after too free potations, seem to be more referable to the aldehydes in the spirit, including furfural, than to the spirit itself or any higher alcohols. Fusel oil was present in the spirit both before and after distillation.

The aldehydes are pharmacologically active, their action depending, according to Loew, upon their combining with the amido groups (NH_2) of the proteid molecule; their antidote, or at least one of their antidotes, is ammonia, which forms with them an innocuous compound. This fact has a bearing upon the subject in hand, for the substances which have a reputation amongst alcoholics as "morning pick-me-ups" contain either ammonia or simple or substituted amido groups, or just those groups which are capable of neutralising aldehydes. If the residue which is left behind after distilling the spirits with phenyl hydrazine sodium sulphonate be treated by appropriate methods the aldehydes are liberated. It is to the pharmacological action of this distillation residue that we are at present directing our attention, and we hope to be able to publish our results with it shortly, as well as a more exhaustive account of those enumerated above, with the literature of the subject.

SUGGESTIONS FOR THE PRACTICAL TREATMENT OF TYPHOID FEVER.

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

UNTIL the time shall come for the prevention and cure of typhoid fever by germicides the chief objects of our treatment should be: (1) to limit the extension of the ulceration; (2) to treat the ulcers; and (3) to obviate their giving rise to hæmorrhage or perforation. For the present my remarks must be limited to the medical aspects of treatment.

Stagnation of putrid fæces is probably one of the chief dangers. Though it may be to a great extent prevented it is often overlooked. When stagnant the more fluid are the fæces so much the more likely are they to lead to toxic absorption. Whilst, then, there is an indication for reducing their fluidity, there is undoubted advantage in any method which provides for their ready evacuation. The difficulty lies at the seat of ulceration, where the accumulation due to paralysis of the bowel may amount to obstruction. Much of the alarming tympanitis of bad cases is probably due to the resulting fermentation in the delayed intestinal contents, and this points to the importance of emptying the cæcal pool. On the whole, a lessened fluidity or a moderate solidity of the contents of the lower bowel would seem to be preferable to the opposite extreme, which is a characteristic of the worst forms of typhoid fever. The lesser evil of constipation incidental to an astringent treatment is one easily overcome by daily injections. Due attention to these essential points might perhaps have yielded better results from the various antiseptic remedies which have been tried and subsequently discarded. For the treatment of enteric ulcers, as for that of ulceration in general, an adequate alimentation and local sanitation and antisepsis are the first requisites. If any local effect can be obtained from the internal administration of medicines some mildly astringent influence is apparently the best and the same is also indicated as a prophylactic against hæmorrhage.

Relative inactivity of the liver is the inevitable consequence of the pyrexia, of the immobility of the patient, and of an exclusively fluid diet. Much of the value of Brand's treatment is, I believe, due to the relief which it affords in that direction. Systematic cool sponging is also efficacious and it is available in all cases; whilst high temperatures may call for the gentle use to the skin of ice wrapped in flannel. But in my experience the cool bath is rendered unnecessary by the administration of mercury which excels all medicinal antiseptics in being at the same time a powerful hepatic stimulant and in providing for the bowel a sufficient supply of its normal antiseptic the bile. We should not lose sight of the mechanical factors. Our anxiety to avoid peristalsis may have been excessive. *Distension* of the thinned and ulcerated membrane is the real danger. In view of a possible hæmorrhage or perforation moderate contraction of the bowel is the better state and is in itself protective, though active peristalsis is obviously to be avoided. An attempt to carry out some of these principles is contained in the following suggestions, which for the sake of brevity will not include any reference to diet and to nursing, as these matters are now receiving greater attention and are better understood.

The postural treatment.—Often in the course of an enteric attack there is obvious fulness and tension and extensive dulness over the right iliac fossa, and a sensation of weight will be conveyed to the hand when placed behind the loin, whilst the left iliac fossa is soft to the touch and resonant. Now it will be found that if the patient be placed for a few minutes on his left side and once more examined in the supine posture the conditions are entirely reversed, the right flank being resonant and soft and the left iliac fossa or the descending colon dull and resistant. Repeated observation of this result has for the last three years led me to arrange the bed so as to keep the patient at intervals, or in some cases permanently, in a position of slight inclination towards the left. *A partial lateral decubitus* which I have usually found to be sufficient for the purpose may easily be obtained by placing a bolster or a firm pillow under the right side of the mattress so that the body is propped over towards the left. A better method, which has the advantage of not disturbing the patient, consists in inclining the bedstead by blocks of suitable height placed under its two right feet, whilst the patient maintains the dorsal decubitus. Inasmuch as a slight elevation of the foot of the bed is a decided help, a double inclination may be obtained by using three blocks of uneven heights. The bed in this case looks uncomfortable but I have not heard of any complaint on the part of the patient. Either of these methods will fulfil an indication of the first importance by emptying the cæcal pool which I regard as an obstruction and as responsible for fæcal stasis higher up and for the toxic typhoid state. When the first method is resorted to there is no object in its being enforced continuously so long as the state of the bowel is carefully watched and the cæcum and lower ileum are kept empty. In anxious cases the other plan is decidedly to be preferred and should be kept up during the period of danger. The methods in question are, in my experience, free from risk and from appreciable discomfort and I have not been led to suspect that any undesirable strain is thrown upon the diseased bowel.

The medicinal treatment.—The remaining indications have appeared to me to be best carried out by the treatment recommended some years ago by Mr. W. B. Wedgwood of King's Lynn. Though it will not avail against the fatality of the worst attacks it has, so far as I have been able to judge, mitigated the severity of the great majority of cases, and has almost always led to an early amelioration manifested by the disappearance of sordes, the cleaning of the tongue, the clearing of the complexion, and, above all, the return of the appetite. For an adult 20 minims of the liquor hydrargyri perchloridi and from 15 to 20 minims of the tinctura ferri perchloridi with one drachm of syrup of orange or lemon and an ounce of water are administered every six hours throughout the attack, and for 10 days after defervescence to obviate a relapse. Diarrhœa, if present, is quickly stopped, except in the worst cases, and the constipation which often ensues and coincides with an excellent progress is remedied by daily injections of glycerine. The results have been so satisfactory that the administration of alcohol is hardly ever necessary and is carefully avoided lest it should dull the appetite or burden the liver, but port wine is invariably given during convalescence. In the now considerable series of cases treated in this way salivation has never been observed, and the treatment is always well tolerated provided the dose is administered at an interval from milk meals, even should, as is my invariable rule, the milk be peptonised.

To which of the ingredients the greater share of usefulness belongs it would be hard to say. In my opinion they are both valuable. An astringent effect of the iron upon the entire intestine is rendered probable by its constipating effect upon the lower bowel. We may, therefore, reasonably assume that it acts as a local application to the ulcers, whilst it tends to constrict the bowel and its blood-vessels against the risk of hæmorrhage. The many-sided virtues of mercury are probably exerted upon the hepatic, the lymphatic, and the mucous systems, and it is not unwarrantable to suppose that its prolonged administration in frequently repeated doses may be an element in the disinfection of the alimentary canal.

Curzon-street, W.

THE TREATMENT OF A CASE OF ACUTE DILATATION OF THE STOMACH.

BY GEORGE COATES, M.A., M.D. OXON.

THE following case of acute dilatation of the stomach in an infant, three weeks old, who finally recovered and in whom the recovery seemed to be entirely due to systematic washing out and cleansing the stomach, appears to be worth recording. I have called the case one of acute dilatation of the stomach, as that was the main feature, though from the collection of cases of hypertrophic pyloric stenosis in infancy in a paper by Dr. Eric Pritchard[1] I have no doubt that stenosis of the pylorus, either spasmodic or structural, was the cause of the dilatation.

The patient, a girl, was born on Jan. 24th, 1900, and weighed 7 lb. 13 oz. She seemed quite healthy and apparently remained so for nearly three weeks. Her mother endeavoured to nurse her, but failed after trying to do so for some days. She was then fed on humanised milk, from a dairy company. On Feb. 14th she began to be frequently sick. From the 17th to the 19th the vomiting suddenly changed its character: she was sick only once in the 24 hours, but then, the nurse said, a very large quantity, at least a pint, came away soaking all her clothes. At the same time her micturition became very scanty and the bowel contained only small quantities of mucus stained almost black with altered bile. Her stomach was manifestly enormously dilated, whilst from the absence of residue of food in the bowel and the very scanty micturition it was evident that little or nothing passed through the pylorus; but whether there was stenosis of that opening or whether the enormous dilatation of the stomach had produced there such a kink that nothing could pass through it was not evident. The treatment devised was to feed her at intervals of from two to three hours with small measured quantities of food, and one teaspoonful of the following mixture was given after each meal to aid digestion and to try to prevent fermentation from taking place in the dilated stomach: acidi hydrochlor. dil., 25 minims; glycerini pepsini acidi, one and a half drachms; acidi carbolici purissimi, half a grain; aq. ad one and a half ounces. On Feb. 19th Dr. Thomas Barlow saw her with me and confirmed the diagnosis and treatment. On the 28th, as she was slowly but steadily losing ground, nutritive enemata were given; each enema consisted of one ounce of peptonised human milk with two drops of brandy. These enemata were given every three hours until the end of May and, with the exception of a few days when there was some diarrhœa, they were always retained and were absorbed. The bowel was washed out once a day with soap and water. Early in March she had a severe attack of gastro-intestinal catarrh with sickness and diarrhœa. The vomit contained greenish-yellow muco-pus mixed with curds. The stools were frequent and foul-smelling. She had fever, the temperature varying from 99° F. in the morning to 102° at night, and a loud endocardial mitral regurgitant murmur was developed. She lost flesh very rapidly, her weight being 5 lb. 13 oz. on March 17th—a loss of 2 lb. since birth. Her condition at this time looked perfectly hopeless. She was in a state of extreme emaciation, with shrivelled dry skin and a distended abdomen. The front abdominal wall was so thin that the liver area could be distinctly recognised from the dark colour of that organ showing through it. The dilated stomach could also be easily made out, and slowly moving peristaltic waves were seen passing over it from time to time. For a few days milk was entirely stopped by the mouth and she was put on raw meat, meat juice, and warm water as food, and sulpho-carbolate of soda and carbonate of bismuth as medicine. A few days later, as her temperature never rose above 99° and the diarrhœa had stopped, human milk was given as well. On March 19th she had still lost weight, being now 5 lb. 11 oz. at seven weeks from birth, when she ought to have weighed over 10 lb. From her constant loss of weight and general condition it was obvious that she must die unless the state of her stomach could be improved, and as a last resource it was determined to wash it out with a solution of sodium bicarbonate, 25 grains; sodium sulpho-carbolate, 15 grains; euthymol, half a drachm; aq. ad one and half ounces. On March 22nd a No. 12 soft elastic catheter, indiarubber tube, and glass funnel were used; the catheter was passed through the mouth every morning about three hours after a meal. When the catheter entered the stomach some wind would generally escape and then from three to four ounces of thick slime and curdled milk would be evacuated through it. The stomach was then washed out and the resultant fluids were measured. Immediately after the stomach was cleansed a teaspoonful of the following mixture was given: spiritus ætheris chlorici, 15 minims; bismuth carbonate, 40 grains; sodium bicarbonate, 12 grains; sodium sulpho-carbolate, half a drachm; decoctum hæmatoxyli, six drachms; aq. cinnamom. ad one and a half ounces; and a quarter of an hour later she was fed with from two to three ounces of human milk freshly drawn off. She was fed alternately from every two to three hours with from two to three ounces of human milk and one ounce of meat juice. She was not put to the breast as it was considered important that she should have no opportunity of overfilling the stomach. From this time her improvement was decided; she spent very comfortable days but used to get rather restless by evening and was decidedly uncomfortable during the night. The day after the washing out was commenced she began to pass much more urine; three days later and subsequently she had almost normal motions. At the end of March the meat juice was stopped and she was put regularly to the breast. By April 2nd she had gained two ounces. By the 6th she had gained two more ounces. As her nights were so bad and the days were so good she was from this time washed out regularly night and morning at about three hours after ameal. Each time about three ounces of slime and curd were removed. On the 16th she had improved so much that a trial was made to see if washing out in the morning only would do, but her nights became restless again, and the evening washing-out of the stomach was resumed. By May 1st she had gained over one pound, her weight being 6 lb 13 oz She made uninterrupted progress, so that by the 12th the residue of slime and curd removed was reduced to between one and a half and two ounces. After the 19th she was only washed out occasionally. On the 23rd, after 48 hours' interval, only one and a half ounces of residue were found. On the 30th her weight was 8 lb. 4 oz She had improved steadily ever since and on July 17th she weighed over 12 lb. Her heart was now perfectly normal, the murmur having disappeared on March 29th.

---

[1] Archives of Pediatrics, April, 1900.

There were two points that are worth noticing: 1. The patient's sensations of hunger were apparently caused by the absence of digestible food in the stomach She always showed signs of hunger two or three hours after feeding, even though her stomach, as ascertained by the catheter, might contain three or four ounces of slime and curd. After this had been removed, the stomach cleansed, and two or three ounces of milk given, she would appear to be satisfied for over two hours, although the stomach really contained less material than when she was very hungry. Her sensations of repletion depended on the nutritive value rather than on the quantity of the matter in the stomach. 2 Her attack of severe febrile muco-purulent gastro-intestinal catarrh was rapidly followed by the appearance of a loud mitral systolic murmur which resembled in every way one due to rheumatic endocarditis. Soon after the stomach was brought into a healthier condition and the catarrh and fever had subsided, the murmur disappeared, and the heart has since then appeared to be healthy.

Cases of febrile disturbance, accompanied by some gastro-intestinal trouble and followed by excited action of the heart and the development of an endocardial murmur, usually at the mitral orifice, are very common in children, and this case appears to show that the endocardial infection may have entered the body from the alimentary canal. It is always dangerous to generalise from only one case, but this one shows that an extremely severe attack of acute dilatation of the stomach was cured by systematically cleansing that organ twice a day. As the treatment was persevered with the residue of slime and curd became less, and though at first from day to day no great difference could be seen, after every few days it was clear that the food given was being better digested, that less slime was secreted, and that the stomach was in a healthier condition and was regaining its normal functions.

The main point in the treatment appears to be the removal of the residues of slime and curd. This is analogous to the removal of residual urine and mucus in cases of aggravated catarrh of the bladder where the prostate is much enlarged. These residual fluids kept at the temperature of the body form most excellent incubating media for various species of bacteria and promptly infect and contaminate any fresh liquids, whether milk or urine, added to them. Drawing off the residual fluid and washing out the stomach in this case were quite as satisfactory in their results as emptying and washing out the bladder are in these cases of cystitis. Here I may mention that there was some difficulty in getting the catheter to pass the larynx and to enter the œsophagus, but with a little patience it could always be done. Towards the end of the treatment, when the stomach had been restored to a healthy condition, it was evident that it had regained its power of emptying itself through the pylorus. The child had regular natural stools and since then has shown no signs of having an abnormally large stomach or narrow pylorus. I have to thank Dr. Barlow for his valuable aid in February and March.

Brechin-place, S.W.

A CASE OF COMPLETE TRANSVERSE SEPTUM OF THE VAGINA IMPEDING DELIVERY; URETHRAL COITUS.

BY E. RUMLEY-DAWSON, L.R.C.P. LOND., M.R.C.S. ENG.

THE patient was a primipara, aged 21 years, to whom I was called when in strong labour. Her history was as follows. She had had scarlet fever when she was six years of age, but her mother had never mentioned that the attack was in any way unusual, neither had she any recollection of pain or discomfort on sitting down or on micturition. She had never received any injury in the genital region. She had always been regular in her menstrual periods and they were not excessively or abnormally painful. She had never had any symptoms to lead her to think that there was anything abnormal in the vagina. She always had some leucorrhœa but had not seen a medical man for it. The nurse noticing that in spite of strong labour pains no progress seemed to be made at last sent for me.

On examining the patient in the left lateral position the index finger unknowingly and without pain passed direct into the bladder. On more deliberate and ocular examination the external genitals were quite normal but the urethral orifice was found to be very dilated, while the vaginal orifice was small. The finger passed less than an inch into the vagina, meeting with an obstruction which, when a labour pain set in, felt like a large "bag of waters," and bulged with the pain. No cervix could be found and no fornices. The child's head could be felt per vaginam to be pushing down on to the obstruction and making it bulge. On examining per vaginam and rectum it was quite easy to get the obstruction between the fingers. It was found to be a rather thick transverse septum or diaphragm; this could also be plainly felt on examination per urethram and vaginam. The septum between the finger-tips was felt to be about one quarter of an inch thick at the insertion into the vaginal wall, thinning down to the centre and becoming thick again at the opposite vaginal insertion. It was evident that a complete transverse vaginal septum was preventing the descent of the head. No hole or aperture could be found anywhere in the septum, but no examination under an anæsthetic was made. The bulging down of the septum by the advancing head so stretched it that even a small hole would have been revealed. The septum was not in the site of the hymen.

Though the patient denied being aware of any abnormality, sexual intercourse it was admitted had been difficult from the first; while several months after marriage it became impossible, still later there had been less difficulty as the urethra was gradually dilated. The dilatation of the urethra had followed as the result of repeated attempts at coitus; she had not, however, been troubled with incontinence of urine, though urination had become more frequent. This increased frequency may have been partly or even entirely, due to the pressure of the enlarged pregnant uterus. The septum was incised with a knife between two "pains," the incision was then enlarged with a finger tearing it through, the "waters" were ruptured, and the child very shortly after was delivered quite easily and naturally.

Remarks.—Cases of transverse septum of the vagina are distinctly rare, and when leading to urethral coitus, and later impeding labour, they become still more rare. Vaginal septa are either transverse or vertical, but only the former will be considered now. Transverse vaginal septa are either congenital or acquired—i e., inflammatory in origin. The one now described was evidently congenital, for though she had had scarlet fever there was no history of genital inflammation.

Dr. C J. Cullingworth[1] has recorded two cases of transverse vaginal septa. The first case, that of a widow, aged 38 years, was due to an attack of "inflammation at the age of 12 of the genital organs." There was an opening in the "thin and flexible septum" large enough to admit a uterine sound. Though she had been married nearly six years she was never pregnant and was "not aware of any difficulty or inconvenience in her marital relations." In the second case the septum obstructed labour; it was evidently a congenital case. There was always slight leucorrhœa, and pain at the periods was "excessive" during the previous three years on the first day only of the flow. Under ether an opening of the size of the urethra was found in the septum, this was dilated and torn through, delivery soon following.

Dr. Cullingworth remarks that probably in all cases of transverse vaginal septa there is an opening, though often very small, and these small openings show how very enterprising the spermatozoa are. Further, he says that, "as in many other forms of vaginal abnormality, the urethra is often found much larger than usual"; possibly in his case also coitus had taken place per urethram. In atresia hymenalis it was pointed out by Oldham that the urethral orifice is more patulous than it is normally. Dr. C. R. Prance[2] records two cases of transverse vaginal septa. Neither of the patients were pregnant; the first was unmarried and the second was married but was sterile; she soon became pregnant after the opening in the septum—of the size of a pin-hole only—was enlarged and the septum was destroyed. Dr. Gervis[3] also narrates a case. The patient was a woman, aged 22 years. There was an annular hymen which was fairly defined, so that the septum was not a misplaced hymen. She had constant leucorrhœa in the intervals of her menstrual periods. A small probe only could be passed through the hole in the septum, which was very thin. "Whether it was congenital or due to early adhesive inflammation it was difficult to decide" Dr. Cullingworth[4] in his paper says that the septum usually consists of "a thin, not very vascular, and easily lacerable membrane." Dr. R. S. Fancourt Barnes[5] gives a case of a primipara, aged 21 years, where a "thick septum at least two inches in thickness existed." There was a small hole which admitted a uterine sound when some pressure was exerted in its introduction. The septum impeded labour.

These cases of vaginal septa are quite distinct from cases of cicatricial contraction or occlusion of the vagina. These latter have led to Cæsarean section to remove the child when the vagina has been so obliterated as to prevent birth per vaginam. Such a case was narrated by Staude in a paper on Cicatricial Contractions of the Vagina Impeding Labour. It led to an interesting discussion of the subject and its etiology.[6] Dr Galabin has recorded a similar case[7]

Concerning the dilated condition of the urethra, the result of admitted urethral coitus, most of the recorded cases of the latter have been in instances of *absent vagina* In THE LANCET[8] of 1869 it is mentioned that Dr. T. A. Emmet in his book on "Vesico-Vaginal Fistula" (1868) records two cases of coitus per urethram. In both cases the uterus and vagina were absent. The urine was easily retained in spite of the dilated urethra, "which was so patulous that the index finger could be introduced without difficulty" in one of the cases, while "in connexion the bladder had been entered without either party being aware of the malformation." Dr. J. C. Gooding[9] records a case in which the lower portion of the vagina was undeveloped. The retained menses had burst through the urethra. The bladder could be entered with the greatest ease, even with two fingers, and this digital examination of the bladder was painless. There was no incontinence of urine. The patient was married and coitus was followed by immediate desire to micturate. Professor Langenbeck[10] recorded the following case. The patient was 23 years of age; menstruation began at the age of 14 years and the discharge took place per urethram. She had been married for three years. "Coitus was effected by the urethra." The vagina was entirely absent and the uterus was rudimentary.

In the case the subject of this paper the vagina was *not absent*, and it subsequently fulfilled its function as the parturient passage, but the transverse septum in it prevented its proper use in coition and led to the urethra becoming used and consequently dilated. There can be no doubt that previously to, and just after, marriage there was an opening in the septum by which the menses escaped and by which eventually the spermatozoa were able to reach the uterus. That the patient became pregnant must have been due to intercourse having occurred per vaginam. Subsequently to impregnation on an occasion of forcible coitus, perhaps even the identical occasion of her impregnation, the opening in the transverse vaginal septum must have been torn; its edges thus freshened would be approximated by the collapse of the vaginal walls; this tear then evidently eventually healed up, so that at the time of labour no opening on examination could be detected Thus the upper part of the vagina and the already impregnated uterus became completely shut off. Urethral coitus must have followed as a result of this practical occlusion of the vagina, which probably became more and more marked as towards the latter half of the pregnancy the increasing size and weight of the fœtus and uterus helped to force and bulge down the vaginal septum and thus entirely obliterate the vagina for practical purposes. So patulous had the urethra become that the index finger passed quite easily and painlessly into the bladder.

Leyton, N.E

AN OBSCURE AND COMPLICATED CASE OF CARCINOMA OF THE STOMACH.

CHARLES FRANCIS STEELE, L.R C.P. LOND., M R C.S ENG.

CASES of carcinoma of the stomach, which are more or less atypical, are not uncommon, but it is, I think, rare to find practically none of the cardinal symptoms present, as in the case which I am about to describe, especially when the disease is well advanced. The patient was seen during his last illness, to my knowledge, by seven medical men, yet—and I think not unnaturally so—the real state of affairs was not diagnosed, or indeed suspected, until the day before his death. In addition to the obscurity of its diagnosis the case presented interesting complications.

A well-to do man, aged 46 years, consulted my father, Dr. Charles Steele, for the first time on August 1st, 1900, complaining of debility and depression, also of pain in the lower right chest and behind the lower right ribs, which was aggravated by gentle pressure. The hepatic region was tender in front, but the liver itself was not enlarged. The tongue was coated with a yellowish fur. "*Rheumatic*" pains in the shoulders, the upper arms, and the pectoral regions were complained of. His general condition was a good deal relieved by saline aperients and rest in bed, and on August 12th he was able to sit up and take food, which he much relished. It was suggested that when he became stronger a "course" at Droitwich might prove beneficial. In consequence of this remark the patient, a self-willed man, insisted upon going forthwith to Droitwich, and he went there on August 16th. The reports from his medical adviser there were not encouraging; the weakness progressed steadily, and after a stay of 18 days he was prevailed upon to return to his home. At Droitwich, by reason of the marked and increasing weakness, and also the presence of several fawn-coloured patches on the right chest in front and on the back and legs, his malady was diagnosed as Addison's disease. No nausea or vomiting was complained of.

[10] Brit. Med. Jour, vol. ii., 1879, p 61

It was at this stage (on Sept. 4th) that the case came under my care, Dr. Steele being away on his holiday. I found the patient in bed, lying on his back. He had apparently stood the journey well. He was of slight build, of dark complexion, and of somewhat anxious expression. The sclerotics were slightly jaundiced, the mucous membranes were markedly anæmic, and the tongue was coated with white fur. During my examination he complained bitterly of pain in the back and chest when turning on his side or when sitting up. On looking at the coloured patches I concluded that those on the legs, being scaly, were due to an old psoriasis of which there was a history; the other patches on the chest and back were caused by the microsporon furfur and faded without treatment. Over the lower right ribs was a distinct bulging, the intercostal spaces being obliterated. The bulging was of about the size and the shape of a small inverted saucer, and it was bisected by the anterior axillary line. Pressure over this area caused considerable pain, which was most intense at one particular spot. On percussing over this bulging the note was deficient in resonance and a distinct thrill was felt. With this exception nothing abnormal was found in the chest. There was no cough. The heart sounds were normal. The pulse, which was full, was regular and of high tension; it was 120, and at no time did it fall below this until his death. The temperature was 100·2° F. and it oscillated slightly above and below this, being at its highest at night. The urine was normal in appearance and there was no albumin or sugar. The bowels were confined. The limb muscles were flabby and wasted. There was no nausea or pain after food. As Dr. Steele also had found, the abdominal muscles were held so rigidly contracted and pressure caused so much discomfort that a satisfactory examination of the abdomen could not be made, but no growth was felt. I concluded that a cyst, which was possibly hydatid but also conceivably of a cysto-sarcomatous or simple nature, was present either in the upper and anterior part of the right lobe of the liver or else between this and the diaphragm. On the following morning in consultation an exploring-needle was thrust into the bulged area and about a drachm of clear pale yellow fluid was withdrawn. An exploratory incision was advised with drainage of the cyst, should such be found, but to this the relatives would not consent. The treatment was therefore purely symptomatic: pain was greatly relieved by morphine and the bowels were kept active by soapy water and turpentine enemata. The swelling appreciably diminished in size, but the wasting and prostration still continued.

On Sept. 16th Dr. R. Shingleton Smith, physician to the Bristol Royal Infirmary, saw the patient with me. At this stage he was in a very critical condition, being intensely anæmic, prostrate, and quite helpless. He lay continuously on his back, apathetic, and listless, and he still complained greatly of pain when he was shifted on to either side or when he was held sitting up in bed. Neither at this time nor during his illness was there any nausea or vomiting, and his food—broths, meat essences, milk, &c.—was well taken and retained. The abdominal muscles were so wasted and the general debility was so great that a much more thorough examination of the abdominal viscera was possible than had been the case heretofore. On pressing deeply beneath the left costal margin two hard lumps of the size of walnuts were to be felt placed side by side but separated by a small interval. A diagnosis of carcinoma of the stomach was made and a hopeless prognosis was given.

In answer to leading questions bearing on the diagnosis the following points in the past history were brought to light. Two years previously a medical man had been consulted, the patient being away from home for change of air, and he had stated that there was a "growth beneath the heart," and on the patient expressing doubt the medical man had exclaimed: "I can feel it as distinctly as I can feel the watch in my waistcoat pocket." It does not appear, however, that he expressed any opinion as to the nature of the growth or mentioned the stomach in connexion therewith. Six months later a quantity of "corruption" was brought up. The medical adviser then consulted considered that the patient had been poisoned, but nothing of this sort ever recurred. Six months later bleeding from the anus occurred, evidently due to piles, which were operated upon, and the bleeding ceased forthwith. There was no history whatever of any nausea or vomiting or pain in the epigastrium, though he had at times complained of uneasiness after food. Only within three months of death had there been any weakness or wasting.

At the necropsy, which I made on the afternoon of Sept. 17th, death having taken place at 6 A.M. on that morning, I found the liver very adherent to the parietes excepting over the area corresponding to the bulging on the surface. Why there should have been so much pain and swelling in this region I do not pretend to know, but I can only suppose that an "adhesion cyst" existed which had been induced to absorb by the drachm or so of fluid withdrawn by the exploring needle. The liver was not enlarged and showed nothing abnormal beyond a thickened capsule. The stomach was not adherent or dilated and the entire length of the lesser curvature was felt to be occupied by a hard mass. The stomach, after ligature, was removed and opened. The contents, three or four ounces, consisted of a pale yellow, thickish fluid. There was no blood. The cancerous mass measured four inches long by two and a half inches wide and it was about one inch in thickness; the pylorus itself was not involved. On the mucous surface of the growth was a large shallow ulcer, measuring two and a half inches by one inch. The edges were blunted and only slightly raised, the floor was ragged, and there was no fresh blood upon the ulcer. The specimen was placed in spirit; it is now in the museum of the Bristol Royal Infirmary. Scattered throughout the great omentum were nodules of growth varying in size from a small pea to a filbert. The pancreas was adherent to the spine, a little enlarged and indurated. The spleen was not enlarged. The kidneys and suprarenal capsules were normal. No other growth was felt. The thoracic cavity was not examined.

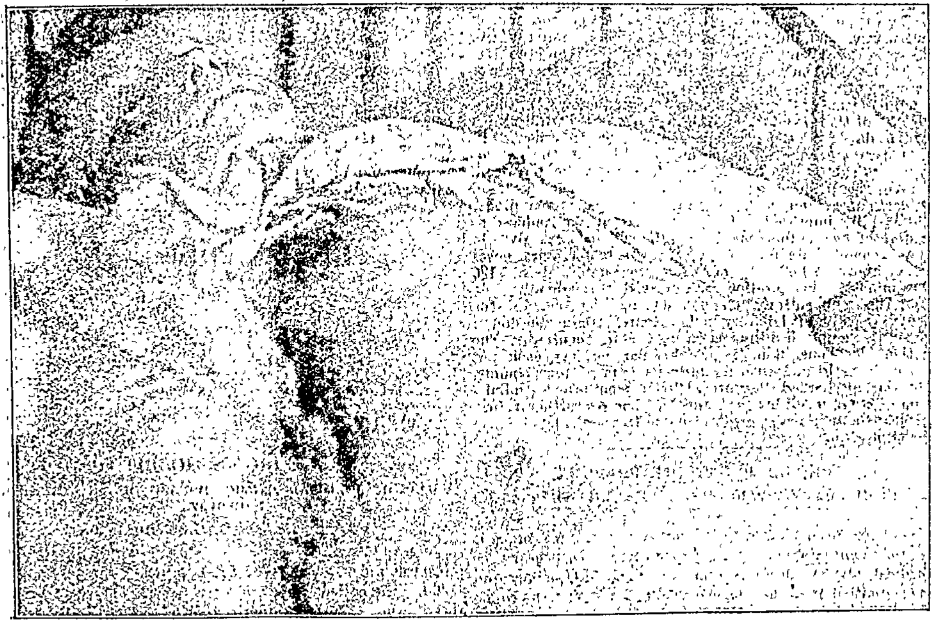
The case is remarkable for two reasons: (1) the condition of the liver, where so little mischief gave rise to so much pain and bulging on the surface; and (2) because, although there was such extensive disease of the stomach, there were so few symptoms to indicate it. It is in those cases where the growth is on the posterior wall of the stomach and does not involve the pylorus that carcinoma is likely to be overlooked. My father informs me that, in his experience, the pain and stiffness on movement, which were so marked in this case, not uncommonly point to malignant disease of, or in close proximity to, the spinal column.

Clifton.

AN INSTANCE OF EXCESSIVE ENTERIC RASH IN CHILDHOOD.

By ARTHUR MAUDE, L.R.C.P. Lond., M.R.C.S. Eng.

The accompanying illustration gives a picture of the plenitude of the rash in a case of enteric fever. The patient was an ill-nourished boy, aged 12 years. The rash first appeared on the tenth day and it reached its greatest development five days after. The spots were then so numerous that an attempt to count them absolutely failed, and a comparison with the excellent plate in Murchison's book showed far more than two spots to one. They numbered certainly many hundreds; they were crowded over the abdomen and the chest, they were numerous on the back, the arms, the thighs, and the neck; they occurred on the cheeks and forehead, and they even invaded the margin of the mucous membrane of the lips. This great intensity of rash lasted from about two to three days and was followed by fresh crops of a few spots for several days more. The spots were typical in every way, though a few were of unusually large size and of unusually irregular oval outline. The type of disease was severe and at the height of the rash the child was extremely ill. The rash was beginning to fade when the photograph was taken. Dr. J. S Tew, the medical officer of health of the West Kent Combined Districts, kindly examined by the Widal reaction for me at the height of the rash. He found marked clumping action with 1 to 40, but the agglutination was not specially rapid, nor



Showing very excessive typhoid rash in a boy aged 12 years. On comparing the rash with the well-known plate in Murchison's work (Continued Fevers) the spots were quite two to one.

were the clumps particularly large. The child was one of a large family of young children, nearly all of whom were affected with severe enteric fever and most of whom had very pronounced rash. Another child had a copious, but not unusual, rash for two weeks; this ceased and the temperature fell to nearly normal for two days, after which a fresh outcrop of rash preceded a marked relapse.

There are certain peculiarities in the occurrence of typhoid rash in children which I have found well illustrated in these cases. The first appearance of rash in children is often earlier than in adults; it occurs frequently by the fourth day. Again, crops of spots may present themselves for a week after a normal temperature has been established. Rash is uncertain in childhood; it is either very pronounced or very slight. Most of the classical writers on enteric fever in childhood (Rilliet, Eustace Smith, Murchison, and West) agree that rash is less frequent and that even in severe cases spots are often quite absent or very sparse. They agree that the spots are less commonly confined to the abdomen and are frequently on the back, particularly about the interscapular region, the loins, and the limbs. This may possibly, however, be due to the facility with which young children, even with enteric fever, are turned about and examined on their posterior aspect.

Another child in my group of cases showed well-marked *taches bleuâtres* straggling faint bluish patches near the umbilicus, having the shape and marginal outline of wet spots on porous blotting paper. It has lately been suggested by Dr. Julius Dreschfeld[1] that such patches are caused by the irritation of pediculi, but with proper deference to so high an authority I must accept the suggestion with profound reserve. By the older French writers, especially Louis and Taupin, sudamina were regarded as very frequent, or even specific, indications of typhoid fever, but I doubt if the opinion would be held now. Probably the patients whom they observed were treated in wards which were kept at a higher temperature than is now customary.

Westerham, Kent.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PSORIASIS WITH INSANITY; THYROID TREATMENT; RECOVERY.

BY H. DE MAINE ALEXANDER, M.D. EDIN.,
ASSISTANT PHYSICIAN, PERTH DISTRICT ASYLUM, MURTHLY, N.B.

THE following case may be of interest on account of two affections for which the thyroid treatment has been advocated having occurred in the same case, the mental affection following the skin disease.

A man, aged 33 years, was admitted into the Perth District Asylum on March 3rd, 1898. His history was as follows. He was a servant in a country house. He had developed psoriasis eight months previously and was treated medically without much improvement; indeed, the disease progressed. His life being rendered unbearable by the taunts of his fellow-servants and mental depression ensuing he had to leave his situation. He wandered about the country for a day or two and then gave himself up to the police as he was "frightened" of himself and had suicidal feelings. He was certified as insane and was admitted to this asylum. He had suffered no previous illness and there was no history of intemperance. His father and mother had both had rheumatism. Psoriasis was well marked on the extremities, the buttocks, and the back; it was more diffuse on the chest. Itchiness and hyperæmia were well marked. The scalp was in a seborrhœic condition. The bodily health otherwise was of an average character. He was depressed, suspicious, inclined to impulsiveness, and he asserted that he was suffering from "the bad disorder" and that his body was "crawling with lice"—due probably not been successful in meeting with cases of the disease. He would like to ask whether Mr. Corner and Dr. Singer had referred to two separate bacilli as the cause of the gangrene and whether the different cases referred to were due to separate bacilli or were they only varying stages of virulence of the same organism.—Mr. C. A. BALLANCE congratulated Mr. Corner and Dr. Singer upon the interest of their communication. He should not be inclined to perform amputation before making a bacteriological examination, if there were means of finding the bacilli at hand. Mr. Corner and Dr. Singer had referred to the fact that Sir George Humphrys treated such cases without dressing. He would like to remark that that surgeon treated all his cases without dressing, leaving the wound exposed to the air. The results he obtained were comparatively good, bearing in mind that it was in the days before Listerian surgery.—Mr. CORNER, in reply, said that there were only three kinds of bacilli recognised. The bacillus aerogenes capsulatus was the commonest.

Dr. S. BONTOR read a paper entitled a case of Non-malignant Cancer of the Breast. The patient, who had died at the age of 77 years, had had the growth in the left breast 23 years It never ulcerated or gave pain, but latterly there had been some inconvenience from the sense of constriction of the chest. There were several secondary deposits in the right breast and in the skin over the abdomen, but there were no enlarged glands, or signs of involvement of distant organs. The growth commenced as a hard lump in 1877 when she was 54 years of age. The skin became very scaly. She died from asthenia. There had been many cases of chronic cancer recorded but all had ended from extension of the growth. This case showed no signs of extension or glandular affection. The cancerous nature of the growth was assured by both macroscopical and microscopical appearances.—The PRESIDENT remarked that the case was a typical one of atrophic scirrhus lasting a long time and besides the fact that there was no internal reproduction it did not present anything very unusual. He called to mind a similar case which had lasted for 14 years and then a sudden outburst had taken place. In another after an interval of nine years an acute outburst of carcinoma had occurred after an attack of influenza. It would be interesting to know what explanation there was of such long quiescent intervals.—Mr. BALLANCE referred to a case resembling that related by Dr. Bontor. The patient developed carcinoma at the age of 70 years in both breasts. The disease had no effect upon her general health and she did not die until she reached the age of 82 years. It was a well-known fact that carcinoma supervening in the aged was a process of slow growth.

Mr. ALEXANDER G. R. FOULERTON exhibited macroscopic and microscopic specimens from a case of Endothelioma (hæmangio sarcoma) of the Breast and Axillary Glands. The tumour was removed from a woman, aged 59 years, in whom it had existed for three years. The breast and two axillary glands which were removed at the same time were of a uniform deep red colour. The new growth consisted mainly of columns or tracts of cells supported by fibrous trabeculæ. These cells formed the walls of a number of small capillary blood-vessels, from some of which extravasation had taken place. Mr. Foulerton regarded the tumour as an endothelioma of the variety known as hæmangio-sarcoma. He thought that the endotheliomata arising from the cells lining the large lymph sacs—the peritoneum, pleura, and pericardium, the lymph spaces of connective tissue the lymph vessels, and the blood-vessels—formed a definite class of malignant new growth which might with advantage be classified as distinct from the carcinomata on the one hand and from the sarcomata on the other.—Mr. S. G. SHATTOCK suggested that the tumour in question should be referred to the Morbid Growths Committee; he thought that the specimens admitted of a different interpretation to that placed upon them by Mr. Foulerton. He referred to a case published by Mr. H. T. Butlin which presented a remarkable resemblance to that related by Mr. Foulerton. This was the first case published of villous carcinoma of the breast. He had examined the specimens very carefully.—Dr. A. F. VOELCKER quite shared Mr. Shattock's view. They were dealing, he felt sure, with a carcinoma and not with an endothelioma.—Dr. LAZARUS-BARLOW had examined the microscopical specimen and felt convinced that the growth was a hæmangio sarcoma, chiefly on account of the masses of cells around the blood-vessels which were essentially a part of the growth.—Mr. FOULERTON, in reply, remarked that when endothelium took on growth away from its normal environment it might become columnar.

Dr. W. C. BOSANQUET exhibited a Cystic Adenoma of the Left Suprarenal Body which had occurred in a woman, aged 56 years, who had been under the care of Dr. J. Abercrombie at Charing-cross Hospital. She had died from hæmorrhage due to carcinoma of the stomach. The cyst was originally of the size of a Jaffa orange; it lay behind the peritoneum in front of the left kidney with the descending colon to its outer side. The rest of the suprarenal body was adherent to its upper and back part. It was freely moveable in all directions. During life it had given rise to no symptom, the patient having been conscious only of some weight and fulness in the left hypochondrium. It was easily made out on palpation and there was diminished resonance on percussion over it. On incision the wall of the cyst was found to be about one eighth of an inch thick and was tensely distended with turbid yellowish mucoid material. Microscopically the wall consisted of an external fibrous layer lined by a varying amount of cells similar to those forming the suprarenal cortex. The right suprarenal body was the seat of a small adenoma. A few instances of similar cysts were recorded in the Transactions of the Pathological Society; it was curious that those occurring in women were all situated on the left side.—Dr. VOELCKER remarked upon the fœtal rests found within the kidney having a structure resembling the suprarenal bodies.

Dr. HUGH THURSFIELD showed a specimen of Primary (?) Sarcoma of the Stomach in a child nearly four years of age. The child had growths which appeared later than that of the stomach in the jaw and in the thyroid gland. These could not be examined post mortem, permission being refused. The stomach was dilated and enormously thickened, the walls in some cases being fully three-quarters of an inch thick. Microscopical examination showed it to be a small round-celled sarcoma. Records of new growths of the stomach showed sarcoma to be very rare as a primary growth and uncommon even as secondary growths; the usual form that the growth took was that of isolated nodules rather than of a diffuse growth. Four cases had been recorded in the Transactions of the Pathological Society, and a stomach strikingly similar was preserved in the Museum of the Royal College of Surgeons of England, but with these exceptions there did not appear to be any specimen resembling the present on record and almost certainly none in so young a child.—Dr. VOELCKER drew attention to a case of sarcoma of the stomach recorded by Dr. Sidney Martin in the reports of the Middlesex Hospital for 1890 or 1891.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 15th, Mr. J. RUTHERFORD MORISON, the President, being in the chair.

Dr. D. DRUMMOND related the history of, and exhibited, a young man, aged 26 years, who eight months ago was admitted into hospital in a Condition of Extreme Lethargy and who had continued in this condition, displaying no sign of sensibility and no reaction to stimuli of any kind, until two or three weeks ago, when he first showed signs of consciousness of his surroundings and displayed return of muscular movement, first by masticating food and later by movement of the hand and arm and monosyllabic speech. During this period of seven and a half months the temperature, pulse rate, and respiratory rate were all subnormal; the reflexes were diminished. Nutrition had been maintained by feeding through a pharyngeal tube and by massage.

Dr. G. R. MURRAY showed a case of Paroxysmal Hæmoglobinuria. The patient was a man, aged 25 years, who had malaria five years ago and had also had syphilis. For the past two years he had worked as a river boatman. Two years ago, after having fallen into the water, he had his first attack of hæmoglobinuria, since when attacks had been frequent in winter and rare in summer. The man was now anæmic and displayed slight enlargement of the spleen. After exposure to cold he felt chilly, had aching pain in the loins radiating forwards, and passed only one small sample—two or three ounces—of dark porter-coloured urine. At these times the temperature rose to 101° F. During and after attacks the red blood corpuscles were much diminished as compared with previous counts.

Dr. R. A. BOLAM gave a Lantern Demonstration of the Spectra of the various Pigments which might be observed in Specimens of Urine. With reference to Dr. Murray's case he demonstrated the pigment to be methæmoglobin and the deposit to contain large quantities of oxalates.—Dr. DRUMMOND, the PRESIDENT, Dr. T. BEATTIE, and Dr. BOLAM took part in the subsequent discussion.

Dr. VICKERMAN H. RUTHERFORD showed four cases of Lupus after Treatment by Roentgen Rays. The extent and duration of the disease had been variable and in one there was also consolidation of the right apex. Some of the cases had shown slight improvements but in none could he claim cure.—Dr. F. O. COLEY referred to another method of treatment—namely, that of sunlight, the heat rays being intercepted by blue glass. Recovery, in his experience, had been incomplete but gave an encouraging degree of success.

Dr. D. W. PATTERSON (for Dr. J. LIMONT) exhibited the following cases: (1) Morphœa; (2) Lichen Ruber Planus; (3) Figured Specific Rash; (4) Cheiro-pompholyx; (5) Dermatitis and Staining from Lyddite; (6) Fibroid Tuberculosis Cutis; and (7) Pityriasis Rosea.

Dr. H. B. ANGUS showed a patient after Plastic Operation on the Musculo-spinal Nerve—a boy who 16 months ago from fracture of the middle third of the humerus had his musculo-spinal nerve involved in the callus. Operation was performed three months ago; the nerve was freed, a strip of muscle being interposed between it and the bone. The boy now showed complete recovery from previous paralysis.

Dr. ANGUS also showed the result of Extensive Compound Comminuted Fracture of the Lower End of the Humerus. The patient was a boy who had sustained a year ago a severe crush in a coal-pit with extensive laceration of the soft parts, separation of the lower epiphysis of the humerus, and comminution of the diaphysis. He had been sent to hospital for amputation. Two inches of the shaft were excised and wired to the lower epiphysis, the wound having been cleansed as far as possible. A useful and almost perfect arm was the result.—A long and interesting discussion ensued as to the septicity or asepticity of coal-dust, in which Dr. J. ADAMSON, Dr. W. ROBINSON, Dr. MURRAY, Dr. A. H. DAVIS, Dr. I. G. MODLIN, Dr. H. P. BENNETT, and Mr. G. G. TURNER took part. The colliery medical officers alleged that dust from the virgin coal was aseptic.

Mr. J. D. WARDALE exhibited three cases illustrating Various Degrees of Involvement of the Orbit, some of which had been treated by excision and others by caustics, but all of which had recurred.—The PRESIDENT, Mr. A. M. MARTIN, and Dr. BOLAM discussed these cases, the last-named asserting that the reason for local recurrence in cases of rodent ulcer was that surgeons went wide rather than deep.

Mr. WARDALE also brought forward a patient who exhibited Double Dislocation of the Lens, the one forward into the anterior chamber and the other backward into the vitreous.

Dr. ANGUS (for Dr. G. H. HUME) exhibited a specimen of a Large Hydronephrotic Kidney from which 146 ounces of fluid had been aspirated previously to removal. There was a history of injury but he rather regarded the condition as congenital. The boy also exhibited two plates of cartilage at the sites of the third branchial clefts. His mother and sister had the same congenital defects.

Dr. BEATTIE exhibited two similar specimens of Enormous Sacculated Aneurysm which had both sprung from the anterior and convex surface of the junction of the ascending with the transverse arch of the aorta. The one had eroded and pointed through the manubrium sterni, the other through the ribs and costal cartilages to the right of the sternum. Both sacs contained a large amount of dense laminated clot and both specimens exhibited diffuse specific aortitis. The pressure symptoms in each case were related. The patients had died, one from increasing respiratory difficulty and the other from cerebral embolism.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Nov. 16th at the Evelina Hospital for Children, Mr. R. Clement Lucas being in the chair.—Mr. Alfred H. Tubby showed an infant suffering from Imperforate Anus and Recto-Vaginal Fistula in whom an Anus had been Formed by Operation. When the patient was admitted in March last there was no anal orifice and the motions issued from the vagina. A probe was passed through the vaginal fistula into the distal end of the rectal cul-de-sac, and an antero-posterior incision was made through the skin and underlying tissues on to the point of the instrument. The rectal mucous membrane (exposed by enlarging the incision) was brought down with some difficulty and sutured to the edges of the skin wound. A large rubber tube was inserted into the orifice thus made. The sutures, however, gave way and the newly-made orifice contracted, so that three months later the operation was repeated and an excellent result ultimately obtained. No attempt had yet been made to close the vaginal fistula.—Mr. Clement Lucas, Mr. D'Arcy Power, and Mr. H. B. Robinson discussed the case.—Mr. Tubby also exhibited a Cavernous Angioma which he had removed from a male child, aged five months. It formed a firm mass, of the size of an orange, filling up the left side of the scrotum and extending to the external ring. It had a tough, elastic feel, without impulse or transparency, and diminished in size when steady pressure was applied. On its surface were some convoluted coils which gave the impression of large dilated veins. The testicle lay below the growth, the nature of which was not certainly diagnosed before operation. After removal the tumour was found to consist of venous sinuses embedded in connective tissue and fat. Its main blood-supply was derived from the left corpus callosum of the penis.—Dr. George Carpenter showed a boy, aged three and a half years, with many Subcutaneous Fibrous Nodules. There was neither a family nor a personal history of rheumatism; the child had not suffered from sore-throat nor did he present any evidence of cardiac mischief. The liver and the spleen were slightly enlarged. The nodules affected mainly the extensor tendons of the hands, feet, wrist, and ankles. They appeared at the age of 14 months, and since the patient had been under Dr. Carpenter's observation (September, 1898) they had increased in number. Galvano-puncture of individual nodules had been practised with a considerable measure of success, but no remedy had been found that prevented fresh nodules appearing. Radiograms had failed to reveal any changes in the bones. Microscopically a nodule had been found to be made up of fibro-nuclear tissue. He had met with at least three other cases of nodules without rheumatism, but they had not been under observation so long as the present one.—Mr. Clement Lucas exhibited by skiagram a case of Fracture-dislocation at the Elbow. The patient, a lad, aged 10 years, fell heavily upon his right elbow. There was a complete dislocation inwards of the ulna, which was rotated so that its greater sigmoid cavity faced directly outwards. In addition the end of the humerus was split obliquely so as to cut off a fragment consisting of the external condyle, the capitellum, and part of the trochlea. As the injury resisted all attempts at reduction Mr. Lucas (five weeks after the accident) excised the joint with a view to restore mobility to the elbow.—Mr. F. C. Abbott mentioned an almost identical case in a girl, 10 years of age, who had fallen upon her outstretched forearm, causing a dislocation of the radius and ulna backwards. Failing under an anæsthetic to reduce the dislocation he cut down upon the ulna, sawed through the base of the olecranon process, and found an oblique fracture of the capitellum and external condyle, which had united in a somewhat forward tilted position. Reduction was prevented by callus from that fracture. After gouging away some bone he was able to reduce both bones. The olecranon was then wired and the external wound closed. The patient had regained excellent movement with the exception of complete extension.—Mr. Sydney Stephenson showed, for Dr. Septimus Sunderland, a case of Hygroma of the Neck in a boy, aged three years. A swelling at the angle of the right inferior maxilla was noticed at birth. This had gradually become larger until the present time, when it had become as big as a medium-sized pear and extended to the clavicle.—Mr. Clement Lucas, Mr. Abbott, and others discussed the case.—Mr. Walter Edmunds showed a case of Unilateral Coxa Vara in a boy, aged eight years, who had been noticed to limp for about three years. The right leg could be flexed and extended fully, but abduction was limited. The pelvis was tilted, the great trochanter on the affected side was raised, and the right buttock was widened. A skiagram showed the neck of the right femur to lie at a right angle with the shaft of the bone and the upper part of the shaft to be slightly bowed outwards.—Dr. Wayland C. Chaffey showed an instance of Brachial Monoplegia in a newly-born infant with early rigidity. The facts of the case were as follows. The child, now aged four and a half treatment. Although met with in children this condition was rare in adults.—Dr. W. G. Lowe exhibited an Iron Nut and Screw, with a Circular Piece of Bone, which he had removed by trephining from a man's skull. The man had been thrown out of a cart and had pitched on his head on the hard road upon the nut, with the result that the nut had passed through the skin, had punched out a piece of bone in the region of the occiput, and lay buried in the hole it had made in the skull, the circular punched-out piece of bone lying loose on the surface of the dura mater. The curious part of the case was that the injury gave rise to hardly any symptoms except a temporary dimness of sight and that the appearance of the wound aroused no suspicion that a foreign body had passed through it, this being discovered only at the time of the operation. A fracture of the bone only was diagnosed. The patient made a good though rather tedious recovery.—Mr. W. F Haslam showed a preparation from a patient on whom he had recently performed Gastro-jejunostomy for Symptoms of Pyloric Obstruction. The man, aged 67 years, was greatly emaciated, and though no tumour could be clearly felt it was thought that the case was probably one of malignant disease of the pylorus. Puckering and thickening were felt in this situation at the operation, but the patient was in too feeble a condition for prolonged examination. He died five days after operation from broncho-pneumonia. At the necropsy the pylorus would easily admit the finger and there was an ulcer rather larger than a shilling of a simple nature in this position. The obstruction was evidently the result of violent spasm of the pylorus, due to irritation from the ulcer.—Dr. T. Wilson read a paper on the Varieties and Treatment of Prolapse of the Uterus and Vagina.

PLAISTOW AND CANNING-TOWN MEDICAL SOCIETY.—A meeting of this society was held at the Public Hall on Nov. 15th, Mr. R. J. Carey being in the chair.—After the formal business was disposed of Mr. J. J. Harvey read a paper on Dysmenorrhœa. He divided his cases into the clinical varieties of spasmodic, congestive, and obstructive dysmenorrhœa. The spasmodic form was often a neurosis, the pain being either clonic or tonic and most severe before the flow. The congestive form was commonly due to chronic endometritis and was generally associated with bladder and rectal troubles. The obstructive form was a frequent result of stenosis of the cervical canal, the pain being in direct proportion to the resistance to be overcome. Pelvic peritonitis and hæmatocele were remote effects. For treatment during the attack he recommended a combination of sedatives and anti-spasmodics with hot rectal injections. After the period treatment should be directed to remove any constitutional weakness, such as chlorosis, and a local examination should be made. He cited very successful results of dilatation by sounds, in some of which cases it was found necessary to keep in a stem pessary for a month after dilatation.—A discussion followed in which Dr. J. S. McDonogh, Dr. C. W. Taylor, Mr. Sydney Williams, and Mr. G. Charlesworth took part.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society took place at 20, Hanover-square, W., on Nov. 28th, Dr. J. H. Stowers, Vice-President, being in the chair.—Dr. P. Abraham showed a case of Lupus Erythematosus in a man, with very unusual distribution.—Dr. T. D Savill showed: (1) A typical Adenoma Sebaceum in a young child; (2) a case of Molluscum Fibrosum (some discussion followed the exhibition of this case and an opinion was expressed that it might be classed as an instance of Von Recklinghausen's disease); and (3) a case of Xeroderma.—Dr. Russell Ryan showed: (1) A case of Psoriasis simulating a Syphilide; and (2) a case of Alopecia Areata which had apparently been cured within four months by treatment with a 10 per cent. solution of lysol.—Dr. Walsh showed: (1) A case of Symmetrical Tophi in an elderly man (these were of unusual size and some of them had broken down, forming abscesses); (2) a Senile Pigmented Wart on the Cheek of an old woman; and (3) a photograph of a case of Ichthyosis Hystrix.—Mr. G. Pernet showed, for Dr. Radcliffe Crocker, a case of Psoriasis of somewhat unusual aspect and distribution.—Several microscopical specimens were also exhibited.

THE "Croce di Benemerenza," or "Cross of Merit" has recently been conferred, among others, upon Mr. Francis Murphy, L.R.C P. Edin., medical officer to the English Pilgrimage of Holy Year.

Reviews and Notices of Books.

Food and the Principles of Dietetics. By ROBERT HUTCHISON, M.D., M.R.C.P. Edin., Assistant Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. With Plates and Diagrams. London: Edward Arnold. 1900. Pp. 548. Price 16s.

ACCORDING to the author's acknowledgment the appearance of this book is owing to the students of the London Hospital, since but for their encouragement it would never have appeared in its present form and so the author dedicates the volume to those to whom its contents in a series of lectures were first addressed. The lectures were given at the London Hospital some 18 months ago. The subject of food, its composition, and the principles of dietetics in health and in disease has been dealt with most comprehensively and we have read through the chapters with considerable interest. No pains in making the information accurate have been spared and this is especially apparent in the chapters devoted to patent and proprietary foods, the analysis of which, in a great number of instances, the author has undertaken himself or has had conducted at his own instigation. This section of the subject is one, of course, with which we are intimately brought into contact every day, the purveyors of new foods constantly submitting them for criticism and analysis to our analytical staff. Dr. Hutchison makes abundant references to the figures of analysis published from time to time by THE LANCET, and he acknowledges drawing considerable information in the chapter on Sherry from THE LANCET Commission on that subject. Again, he quotes a number of THE LANCET analyses of other wines, and especially those which are said to be suitable to diabetics and to the gouty. Information on these and related subjects is constantly in demand by general practitioners and Dr. Hutchison has placed this information conveniently at their disposal in the volume before us. He speaks with no uncertain voice of the special foods of various makers; when he can speak fairly and honestly of their merits he does so, and when he cannot he records what in his opinion are their demerits. We quite endorse his remarks on medicated wines. The use of malt and meat wines, he says, can on no grounds be recommended. In the first place, they are not worth the price charged for them, for it is far cheaper, and probably better, for an invalid to get beef or malt extract separately and to use them in conjunction with, if need be, a definite quantity of sound wine of reputable history; in the second place, as we have pointed out, it is open to doubt whether the malt ferment is not destroyed, so far as its digestive action is concerned, by the action of the alcohol to which it is exposed when dissolved in a fortified wine such as port or sherry. We have also explained that it is practically impossible to dissolve the nutrient matters of beef in a liquid containing as much alcohol as port wine does. Dr. Hutchison concludes that the manufacture and sale of medicated wines (coca wine, and others) should be strongly deprecated by the medical profession. In the chapter upon Spirits and Malt Liquors he very properly says that it would be a great mistake to regard spirits as simply mixtures of alcohol and water. This of course applies especially to genuine brandy, for it is well known that the stimulating influence of a real matured grape spirit is due to certain by-products of the type of ethers. On the other hand, whisky is a valuable stimulant where the action of alcohol pure and simple is desired. He speaks very strongly as to the importance of employing genuine liqueur brandy in cases presenting signs of profound nervous and cardiac prostration. We have advanced the same argument again and again in the columns of THE LANCET. Amongst the spirits which possess by-products of an ethereal nature the author mentions pot-still whisky, rum, and genuine brandy, but on page 341 he says that it is the possession of volatile ethers in large amounts which mainly distinguishes brandy from whisky. That is the experience gained in THE LANCET Laboratory, and in modern whiskies we have never found any volatile ethers at all. In the chapter on Tea, Coffee, and Cocoa we note that he remarks that the addition of alkali (to cocoa) is a favourite device, especially with Dutch manufacturers. We doubt if this statement is generally correct. We at any rate have hardly ever found free alkali in cocoa, but we have almost without exception found the presence of an added salt which appears in the ash obtained by igniting the cocoa as carbonate of potassium. On page 140 in describing plasmon he says that it consists of the proteids of milk rendered soluble by combination with bicarbonate of soda. Although plasmon will be found to be distinctly alkaline, and especially a solution of its ash in water, yet no appreciable quantity of bicarbonate of soda will be found. This at least was our experience according to a recent analysis. The chapter on Soups, Beef Extracts Beef Juices, Beef-tea, and Beef Powders is a very valuable contribution and Dr. Hutchison's remarks on the relative nutrient value of these food preparations should be widely known. The same holds good for the chapter on Artificial and *Predigested Foods and Artificial Feeding*. Broadly speaking the work may be divided into two parts: a first in which the composition of all classes of food is considered, and a second in which the principles of feeding in infancy, in childhood, and in disease are carefully discussed. We have said enough to show that the work may be cordially recommended as dealing most instructively with a subject which is not generally studied with that care which its importance demands. Nowadays we are presented with all manners and kinds of food-stuffs, some undoubtedly of value but others undoubtedly worthless, and it is important that all those who are concerned in the subject of dietetics (and who are not?) should have some reliable information upon which to found an opinion. From time to time we ourselves place this kind of information before our readers in our analytical columns as new preparations are brought forward. Dr. Hutchison has collected similar information in his book and the results are up-to-date and ably compiled, while his own views and experiences are entitled to careful attention and study.

The Opus Majus of Roger Bacon. Edited by JOHN HENRY BRIDGES, F.R.C.P. Lond., some time Fellow of Oriel College. Second edition. London: Williams and Norgate. 1900. 3 vols. *Price 31s. 6d.*

NEARLY three years ago[1] we noticed in these pages the appearance of Dr. Bridges's notable edition of the Opus Majus of Roger Bacon. The appearance of a second edition demands a further notice now. The second edition comprises besides the two original volumes a supplementary volume—the third—which gives the results of Dr. Bridges's further labours on the text. He has now collated it with a manuscript unpublished at the time when his earlier work appeared and has thus been enabled to make a large number of emendations. Considerations of expense have deterred the University publishers from reprinting the work, but its editor, with great public spirit, has given us the benefit of the latest lights by issuing a complete list of corrigenda in the form of an appendix to the new volume. The main bulk of the volume consists of a reprinted text of the first three parts of the work in which the emendations of these parts are incorporated. Possessors of the first edition will thus be enabled to complete their texts by merely purchasing the small supplementary volume which constitutes Volume III. of the new edition.

In our earlier notice of this work we directed attention rather to the later parts which deal with the physical sciences than to the three parts now published in an amended text. To these parts of the work our professional prepossessions naturally led us. But the parts now re-published, which deal respectively with the Causes of Error, the Relation between Philosophy and Theology, and the Study of Languages, are by no means wanting in interest from any point of view. Even a topic upon which we look so little for enlightenment from the thirteenth century as the bearing of science on religion yields unexpected interest in Roger Bacon's hands. What, for example, could be more suggestive than his comparison (p. 58) of Apollo with Æsculapius. In his view the deities of the pagans are distinguished men whom superstition has invested in later times with imaginary divinity. According to this theory Apollo was a profound philosopher who first among the pagans taught the art of medicine. All honour to him therefore. But to his son Æsculapius, who enlarged the art and taught it by a better method, still greater credit is due. "For," says he, "Apollo cured by means of incantations and remedies of that class but Æsculapius arrived at his art by experience." This sturdy faith in natural science, notwithstanding the commanding claims of magic and of revelation, is the groundnote of all Bacon's writing It is on this basis that he claims preeminence for Aristotle, who procured authority from Alexander the Great to send 2000 men into various parts of the world to carry on researches into the nature of things, who cleared the errors of earlier teachers and extended the bounds of philosophy, aspiring to complete what the ancient patriarchs had left although unable in his single person to accomplish what he took in hand. "For," adds the author, "human discoveries never arrive at finality" (p. 66).

But we must not now pursue this theme since the work is too full of interesting points to be at all adequately exhibited by illustration in the space at our disposal. One word must, however, be added on the subject of the text. What we have above said will have given some indication of our sense of the indebtedness of scholars to the literary enthusiasm and public spirit which have prompted Dr. Bridges to undertake this labour of love. We should, indeed, regret it if any word of criticism should seem to belie our sense of this obligation or to mar the acknowledgment which we desire to make of a great service worthily rendered to the republic of letters. Yet we must confess to a wish that the editor had allowed himself a little greater freedom in the work of textual revision. At its best a Latin book is tiresome to a modern reader and Bacon's sentences are sometimes obscure. Often long, they are not infrequently rambling and tax the reader's attention to a point at which a consciousness of the mere words deadens his apprehension of the sense. But when to these difficulties there is added some corruption of the text of such a nature as to mutilate the sense the result is distracting. We have noted a peculiarly grievous example of such mutilation on p. 81 where a sentence, or rather words, occur which are destitute of meaning until the words "si quis autem" are supplied from a footnote. We recognise the literary piety which has made Dr. Bridges cautious to a fault in the work of restoring the text, and while we would not blame the temper we must claim the liberty sometimes to differ from him as to where in practice "the line" should be drawn.

LIBRARY TABLE.

French Cookery for English Homes. William Blackwood and Sons. 1900. Price 2s 6d.—Good cookery means that food is prepared in an appetising manner and so, presumably, that it will be easily digested and assimilated. Therefore

[1] Scientific Error, THE LANCET, Jan. 29th, 1898, p. 320.

We may assume that our readers have read the remarkable narrative, but as, like all good clinical records, its value is in its details, which are easily overlooked in the strong general impression of the main facts, we venture to advise them to read it a second time. The patient was an infant seven days old, born prematurely by three weeks. On the seventh day (viz., August 27th) the operation of circumcision was performed. It is simply said of this part of the history that "the child did not breathe well under the chloroform. He lost more blood than usual." In these few words we have doubtless the secret of the condition which was soon to occupy all Dr. Keith's strength and ingenuity for 14½ continuous hours The somewhat unusual features of the case were the slow development of the paralysis of respiration and the failure of heart power which caused the child to become cyanosed and to have repeatedly all the appearances of a dead child. We are not told the exact hour of the operation, but after it the child slept for some hours and awoke in the afternoon looking quite natural. But he did not care to take the breast and at 9 P.M. he became very wideawake and screamed for two hours. On being fed at 11 P.M. he took little milk and was very sick. He slept heavily till 3 A.M. of August 28th, when the nurse noticed that his face was cyanosed and took him to Dr. Keith's room, who found him very ill. Very soon breathing stopped entirely. The saving clause at this stage is that the heart was to be heard beating. Dr. Keith immediately commenced artificial respiration, to which the child, happily, responded; but the improvement only lasted a few minutes, when the child was again apparently dying. The heart became very rapid, the colour was worse, and though artificial respiration was again commenced it was more "from a sense of duty" than from any expectation of success. And to this means of keeping the child alive Dr. Keith devoted himself for the period of 14½ hours. At the end of 12 hours a very feeble attempt at inspiration was noticed. This was only once in a minute, but the intervals grew shorter and shorter; in another hour the child was inspiring entirely. There was yet no attempt at expiration, but the change in the condition of the patient was so marked that Dr. Keith began to hope. In the course of the day a supply of oxygen gas was procured, and the constant play about the mouth of the oxygen produced a decided change for the better in colour, in the creaking sounds which had begun to be audible in every forced respiration, and in the strength of the heart beats. At 5.45 P.M. Dr. Keith was able to discontinue, with an occasional exception, the artificial inflation of the lungs. But he was not yet free from anxiety, so he sent to London for an assistant to watch the case, which continued for four or five days to need the most constant and intelligent attention in the varying conditions which threatened life. At one time the child became very cold. He could not take milk-and-water or effectually seize the nipple. But he could take brandy-and-water of which he was given 20 minims every hour. He had screaming fits with offensive motions. On the 29th the temperature began to rise and on the 31st it reached 105° F. Antitoxin in grain doses was given twice and seemed to act antipyretically. On the interruption of the oxygen inhalation which, perhaps unjustly, was suspected of producing pyrexia, the cyanosis returned and the breathing became shallow. The last shock which this little patient gave to his attendants was so late as 4 30 P.M. on the 31st, when, suddenly, without the slightest warning and after one or two catches in his breathing, the respirations stopped entirely. Artificial respiration, oxygen, and brandy removed the grave condition, and thenceforward the child entered on his convalescence. The skin of the abdomen and upper part of the chest after the prolonged artificial respiration was "like raw meat," but the lesions caused by the successful efforts to save life did not long persist.

Patience and resource are qualities of the highest value to the practitioner. A practitioner without hope should not practise medicine. It is not often, of course, that he is rewarded by such direct life-saving as in the case to which we allude. Nor is it an everyday occurrence for him to meet with circumstances and symptoms so urgent and so apparently hopeless. But the good practitioner will try to anticipate such calls on his help. They are not, after all, rare. Every obstetric case has in it the possibilities of complications which tax all the perseverance of the medical adviser. There is no greater trial to the patience and ingenuity of surgeon or physician than dealing with hæmorrhage or convulsions, and no one of us can ever guess when he may find himself confronted with these symptoms in their most critical form. He is the best practitioner who can hope against hope, who can impose on himself the duty of employing the indicated remedies with perseverance where nature is equal to the task of healing disease with the kindly help of her true servant, the medical man. Such a case as the one recorded in our columns by Dr. Keith refutes the scepticism of those who think that medicine has no power. Such scorners will perhaps tell us what the history of the case would have been without artificial respiration or oxygen or brandy and without the moral and intelligent qualities of the physician who used them in turn.

An inquest held recently at Mirfield in Yorkshire is worthy of note because it illustrates with unusual force and clearness the danger to the public arising from the immunity with which cozeners and impostors ply their trade as long as they extract money from their victims under the guise of healers of disease. The inquiry was held upon the body of the wife of an innkeeper whose death, according to the medical evidence, given after a post-mortem examination had been held, was due to cancer in the breast and secondary deposits in other organs of the body, it being also added, as might be expected, that had the unfortunate woman consulted a surgeon at an early stage of her disease a timely operation would, in all human probability, have saved her life. As a matter of fact, however, she had been attended by a "medical herbalist" who was called as a witness and who himself described the course which he adopted. It consisted in hypnotising his wife and asking her while in a state of trance to diagnose the case and to prescribe. This she appears to have done, stating that the patient was suffering from a cancerous tumour, that it would be possible to "scale it away," and recommending the use of an ointment and medicines which the husband supplied. The "prescriptions" were produced in court, being apparently harmless concoctions of herbs, and it was further elicited that they were varied from time to time while the visits of the patient and the hypnotising process were repeated weekly. At some period during the progress of the disease the herbalist, according to his evidence, recommended the deceased to obtain other advice than his, recognising that the case was one of some gravity. He does not appear, however, to have refused to continue his supply of herbal compounds, and he stated in reply to an expression of natural astonishment on the part of the coroner that he honestly believed in what he did. The credulity of the victim and the effrontery or ignorance of the person claiming to diagnose and to prescribe for cancer by hypnotising his wife—without, by the way, making any personal examination—seem to have surprised the coroner, who, however, could only leave two questions to the jury: whether the death of the woman was accelerated by the treatment which she had received, and whether the herbalist had persuaded her from going elsewhere for treatment. An affirmative answer to the first of these questions would have justified a verdict of manslaughter, and we need not discuss the result of such an answer to the second, as the jury found a verdict of death from cancer, and were of opinion that no blame attached to anyone.

It is possible to wish that a trial at assizes could have followed and served as a warning to quacks at large. If, however, that which the herbalist did or omitted to do in this case did not legally justify a verdict of manslaughter it would be well if the law could be so amended as to strike at the root of the evil and to protect others besides those whose lives may be in danger. Police interference for the protection of the ignorant is not unknown where their pockets are in peril. If a gipsy beguiles a kitchenmaid of half a crown by promising her a dark-eyed husband and other ingredients of happiness we send the gipsy to prison because an Act of Parliament enables us to treat fortune-tellers as rogues and vagabonds. Anyone may deceive his fellow-men or fellow-women into parting with their money as long as he makes a pretence of healing disease and does not claim to possess certain defined qualifications which are not necessary to his trade. If, for instance, a man says or suggests falsely that he is a doctor of medicine in an English university he can be dealt with; but he may profess his contempt for the education implied by such a degree and proceed to trifle with the deadliest diseases with hypnotism, Christian Science, herbalism, and so forth, and no one can put a stop to his lucrative career, not even when the result of his intervention is the loss of a life that might otherwise have been saved. The law, in short, takes care of the kitchenmaid's pocket as long as she risks her money only; when she risks her health or her life as well as her money the law does not interfere.

THE human mind is essentially hopeful and prone to optimism, and hence there comes about a tendency too readily to accept as established that which may at any given time be only a matter of inference. The history of medicine and of much of that which passes for science—surely HUXLEY'S view that "science is nothing but trained and organised common-sense" is a sound one—affords many illustrations of this faith, of a faith which clings tenaciously to the original position despite the evidence which has long since rendered such position untenable. When JENNER demonstrated that practically absolute protection against small-pox could, for the time being, be procured by vaccination, he allowed himself to predict, ere the time necessary for establishing such a proposition had elapsed, that such protection was lifelong. The reaction subsequently caused by the testimony of experience afforded the recalcitrant type of mind its opportunity, but now all sensible people protect themselves by vaccination and revaccination.

Again, when the idea of compulsory notification and isolation was first conceived there were enthusiasts who prophesied that by the application of these two principles certain diseases might eventually be "stamped out." At that time the natural history of infectious diseases was but imperfectly understood. Men thought that such diseases were the sole prerogative of the human race; they ridiculed those whose insight and genius led them to infer otherwise. Moreover, the idea that pathogenic organisms might have a saprophytic existence, or that the time spent by the organism in the human economy might be but a phase in the life-history of such organism, found no acceptance. The last decade of the century has, however, taught us that certain animals and insects may share in the propagation of disease, that pathogenic organisms may here and there maintain their existence in the soil, and that diseases are apt to have their variations in prevalence and intensity altogether irrespectively of what are commonly termed sanitary conditions. All these considerations have had their influence in modifying the position once taken up by those who spoke glibly of "stamping out disease," and now what may be termed the anti-isolationist is found declaring that isolation hospitals are not only useless, but are the centres of all sorts of horrors, so that it would be infinitely better to leave the infectious sick, as of yore, in their own homes.

We have before us a pamphlet written by Mr. E. D. MARRIOTT, a medical practitioner of Nottingham, which expounds this view. It would be useful if Mr. MARRIOTT and those of his opinion would consider the objects and scope of isolation hospitals before denouncing them. If inquiry on the point is made to the Local Government Board no reference to "stamping-out" will be found in the hospital memoranda of that Board. Curiously enough, however, in a Local Government Board report on the sanitary administration of Windsor which has recently reached us and of which a review will be found in our last issue we find crisp pronouncement on the matter. In the opinion of Dr. H. T. BULSTRODE, the author of the report in question, the objects of an isolation hospital are thus to be summarised: (*a*) to minimise the risks of infection from invaded houses to the remainder of the community; (*b*) to enable the sick to be separated from the healthy and the healthy to proceed with their occupation or education as the case may be; and (*c*) to provide for better medical control and nursing than is possible in the or temporary nuisance would not be interfered with. "It was not necessary that substantial damage should actually have been done, but the court would interfere if it could be proved that substantial injury would be caused unless the nuisance that was complained of was stopped." The unfortunate orchids were put out of court altogether, as, "the case ought not to be tested by the effect of the smoke on delicate exotics, but by its effect on an ordinary garden." He was satisfied that in this case the smoke was such that it would cause injury to an ordinary garden, so that the plaintiff was entitled to bring the action, the defendant must pay the costs, and if the occasion should arise the plaintiff could apply for an injunction. It really seems easier to obtain protection from smoke for the plants in a garden if they are only "ordinary," than for the people of some parts of our large towns who are apparently somewhat in the position of the orchids. It would be interesting to know if the Vice-Chancellor would look on human visitors from a tropical clime in the light of delicate exotics, and deny them protection because they were not "ordinary" It is said that in the well-known Crumpsall case Messrs. Levinstein are appealing against the decision by which they were fined at the last hearing of the case.

A RETROSPECTIVE GLANCE.

THE *Westminster Review* of May, 1832, contains an article on "Improvements in Medicine and Surgery" which may be commended to the attention of the rising medical generation. "It is a fact capable of demonstration," says the reviewer of 68 years ago, "that since the healing art reached that point of cultivation which entitled it to the name of science disease has been gradually decreasing both in frequency and fatality. And it is equally capable of proof that the degree of perfection with which anatomy has been studied at any successive periods may be safely taken as the rule by which the progress of all the other branches of the science may be ascertained." Rejecting Sydenham's dictum as to the uselessness of "searching into the bowels of dead and living creatures ...... to find out the seeds of disease," the reviewer emphatically endorses "Baillie's assertion that 'the dead body is that great basis on which we are to build the knowledge that is to guide us in distributing life and health to our fellow creatures'"; and then proceeds to quote the statistics of Sir William Petty "who died," he informs his readers in a parenthesis, "about 150 years since." According to Petty, the proportion of deaths to cures in St. Bartholomew's and St. Thomas's Hospitals was in his time one to seven, whereas in 1741 the corresponding mortality had diminished to one in 10, in 1780 to one in 14, and in 1813 to one in 16. Finally, exclaims the reviewer, "out of 12,494 patients treated in St. Thomas's Hospital 259 only were buried, or one in 48." Some remarks of His Royal Highness the Duke of Sussex are next quoted, among them being the statement "that comparing the value of life as it is now calculated to what it was 100 years ago it has absolutely doubled." The Royal Duke then went on to expose how at one time "the entire half of our population were destroyed by one disease—small-pox." Typhus fever used to "slay one out of every three whom it attacked," but at the time of writing the mortality did not amount to one in 16. Measles, scarlet fever, whooping-cough, and consumption were no longer regarded with extreme terror. From 1799 to 1808 about 27 per cent. of those who became ill with consumption died, but during the succeeding lustrum the mortality fell to 23 per cent., and from 1813 to 1822 it still further decreased to 22 per cent. "As anatomy was more attended to," continues the reviewer, "surgery proportionally advanced. . .... The extreme clumsiness and cruelty with which operations used to be performed could scarcely be credited. Thus, Fabricius of Aquapendente, preceptor of the immortal Harvey, describes what he considered was an improved and easy operation. 'If it be a moveable tumour I cut it away with a red-hot knife that sears as it cuts; but if it be adherent to the chest I cut it, without bleeding or pain, with a wooden or horn knife soaked in aqua-fortis, with which having cut the skin I dig out the rest with my fingers.'" It would be interesting to know with what object the soaking in nitric acid was performed; did the illustrious surgeon thus prefigure the advent of antisepticism? It is a pity he does not say whether he soaked his fingers as well. A concluding observation by the reviewer seems to indicate an amount of knowledge on the part of a certain class of irregular practitioners with which it is not at the present day credited: "It is little more than 50 years ago when Mr. Sharpe, one of the most eminent surgeons of London, denied the possibility of the thigh-bone being dislocated at the hip-joint, an accident which occurs daily and which the merest bone-setter in the kingdom can now detect." The final paragraph of this instructive article is noteworthy: "But it were a task equally difficult and unnecessary to enumerate one-tenth of the achievements of modern surgery (*tempus* 1832); and it were superfluous to add that it is to anatomy, and to anatomy alone, that all improvements in this department can be traced." After three-score and ten more years have passed what will be the opinion of our successors regarding the achievements of modern surgery, *tempus* 1900?

THE BOWEL LESION OF TYPHOID FEVER.

IN another column we publish an interesting article by Dr. T. J. Maclagan with the above title. The writer describes in graphic language the changes brought about in a Peyer's patch during an attack of typhoid fever. Now that in every infectious disease we expect to find a micro-organism in direct causal relationship with that disease there is a tendency to consider that the pathogenic organism is the sole cause of the lesions characteristic of the malady. Thus in pulmonary tuberculosis the bacillus of tubercle naturally holds the most prominent place, but we must not forget that other micro-organisms are responsible for the very active pulmonary disintegration which frequently occurs. So Dr. Maclagan points out that in typhoid fever elements other than the typhoid bacillus have to be contended against. The structures in which the pathogenic micro-organism directs its specific effects are the salivary and agminated glands situated in the submucous coat of the small intestine, and certain changes are thereby produced which essentially consist in proliferation of their cellular and granular contents, with consequent swelling and hardening of the glands. Further, this inflammation is generally sufficiently severe to cause gangrene and sloughing of the affected glands. Dr. Maclagan explains that the direct action of the typhoid bacillus is limited to the glands of the submucous coat and that it has no direct action on the mucous, muscular, or peritoneal coats. But the sloughing process which destroys the glands necessarily also destroys the mucous membrane situated over them. With the process of sloughing and suppuration there come into play other and new morbid agencies and the various forms of cocci associated with these processes. To these new agencies, rather than to the typhoid bacillus, Dr. Maclagan attributes all the more serious complications and all the formidable symptoms, general as well as local, which are apt to show themselves during the third and fourth weeks of the disease. We believe this view of the pathology and bacteriology of typhoid fever to be a sound one, and, as already pointed out, it is analogous to what is found in other diseases. It would likewise lend support to the treatment of typhoid fever by intestinal antiseptics which some authorities so strongly recommend. In this connexion we may also call attention to the views expressed by Dr. Owen Paget in a letter which appears in this issue.

ANNUAL REPORT OF THE IMPERIAL BACTERIOLOGIST TO THE INDIAN GOVERNMENT.

THIS report for the year 1899-1900 has just reached us and is a record of very varied work. The laboratory is, or possibly we should say was, situated at Muktesar, but in September, 1899, most of the buildings with their valuable contents were destroyed by fire and the work of six anxious years was within three hours all done away with. The report is chiefly taken up with experiments and investigations for the prevention of rinderpest. The subject is too intricate to be conveniently summarised here and the matter is not yet fully worked out, but the report shows that protective inoculation carried out with due consideration for the strength of the dose in proportion to body-weight will confer immunity for a period of between 70 and 80 days. Experiments were also made with the locust fungus, but up to the date of the report no data had been obtained on which to found an opinion as to the value of this method of killing locusts. A curious disease affecting horses appeared in Roorkee, but its pathology has not yet been made out. Major A. W. Dawson, I.M.S., attributes the symptoms and death to aconite poisoning. Various other diseases are dealt with, such as "surra," a complaint due to a trypanosoma but one of a different species from that which is responsible for the disease known as "dourine." The whole report will be found to be of extreme interest both to medical men and to veterinary surgeons.

ST. BARTHOLOMEW'S, ST. THOMAS'S, AND BRIDEWELL HOSPITALS AND THE LAND TAX.

A VERY curious case has been decided by Mr. Justice Wills, the plaintiffs being the Lord Mayor and others, the Governors of St. Bartholomew's, St. Thomas's, and Bridewell Hospitals, who sought for and obtained a declaration that property known as Maidstone-buildings, Southwark, belonging to these institutions, is exempt from land tax, the difficulty of the question arising from the fact that for at least 120 years the tax had been paid apparently without demur by the tenants, except in 1835, when it was paid by the governors. The statute originally creating the land-tax (4 William and Mary, c. 1) was passed in 1692, "for granting to their Majesties an aid of four shillings in the pound for one year for carrying on a vigorous war against France," but "vigorous wars" and other calls upon the public purse caused it to be renewed from year to year until in the thirty-eighth year of the reign of George III. the impost was made a permanent one. The original Act, by its 25th section, exempted certain learned foundations and charitable institutions from the payment of the tax, and in particular it was not to charge "any of the houses or lands belonging to Christ's Hospital, St. Bartholomew's, Bridewell, St. Thomas, and Bethlehem Hospital in the City of London and borough of Southwark, or any of them" The following section possibly introduced some obscurity by making lands belonging to some of the institutions enumerated in Section 25 liable to pay the tax if let to tenants, and small verbal alterations were introduced in those Acts which renewed that of 1692 and in the Act of George III. mentioned above which did away with the necessity of renewal, while in respect of some of the foundations the lands exempted by the original Act were to be lands belonging to the "scites of the said Colleges, Halls, or Hospitals." On behalf of the defendant, the surveyor of taxes for the parish of St Saviour's, Southwark, two principal points were raised—namely, that the payment of the tax for so long showed that the land in question had throughout been subject to taxation under the statutes and that the exemption on its true construction only referred to property belonging to the hospitals in the sense of supporting their actual buildings. With regard to the first of these points Mr. Justice Wills in a long and learned judgment declined to make the deduction asked of him, and with regard to the second decided in accordance with what seems to us to be provided in tolerably clear terms by the section, that the lands in question having belonged to the hospitals at the time when the original Act was passed are and should always have been exempt from land-tax, whether let to tenants or not Why the tax was first paid at some time in or about 1780, or possibly before that, we need not speculate; presumably the persons asked to pay, not being connected with the hospitals except as their tenants, were not aware of the privilege accorded, and those who paid it in 1835 paid it as a matter of routine without reflection or inquiry. There is assuredly nothing surprising in the exemption and we are inclined to wonder whether any other charitable institutions may be contributing to imperial or local revenues in ignorance or forgetfulness of public or private Acts under which they might claim relief. It is on the face of it unjust, as we have often urged, that charitable institutions supported by public subscription as such should be burdened with the same payments as private individuals or wealthy corporations existing for the benefit of the members composing them. Hospitals pay rates under a statute passed in the reign of Queen Elizabeth, when charitable institutions did not exercise their benevolence on the same scale as to-day and when their needs were not so conspicuous. Nevertheless, a decision of the House of Lords in 1760 declared them to be exempt from the payment of rates and they continued to be so for more than a century. In 1866 another decision given in a case relating to dock companies declared that hospitals were rateable, and Parliament has never thought fit to rid them of the burden thus re-imposed upon them It is interesting to observe from the case before Mr. Justice Wills that in the seventeenth and eighteenth centuries the legislature recognised the claims of charitable institutions and learned societies for consideration more fully than they are recognised at the close of the year 1900.

POISONOUS GLAZED WARES.

A REPORT recently presented by the United States consul at Mayence includes a warning to purchasers of silvered glass and porcelain which ought not to be overlooked. The silver is applied to certain kinds of this ware by a galvano-caustic process which involves immersion in baths highly charged with cyanide of potassium. The surface thus treated is not perfectly smooth but is covered with innumerable fine cracks. In these the cyanide is absorbed and, it is said, cannot be removed during manufacture, although we should have thought, considering how extremely soluble cyanide of potassium is, that it could be easily washed out. As a natural consequence the use, even the handling, of the ware is apt to be followed by poisonous effects. One firm, it is stated, has abandoned this branch of manufacture because of the danger involved in it not only to the public but to the workmen employed. These glazed products are exported chiefly from Frankfort, Stuttgart, and Berlin. Until some non-poisonous means of plating the goods has been devised it is difficult to see how the very real danger which their use entails is to be avoided. No known process of after-washing can be relied upon to cleanse the minute cracks in the glaze, and even if this were possible, the position of the employés would not be improved. The German official authorities are not slow to interfere with manufactures which are proved to be injurious and they can doubtless be trusted to deal with this matter effectively. In the meantime the purchasing public will do well to regard the timely caution which we have quoted from the *Times* and to abstain from buying the articles in question.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE lectures at the Royal College of Physicians of London for 1901 will be delivered as follows:—The Milroy Lectures will be given by Dr. J. F. Sykes on Thursday, Feb. 28th, Tuesday, March 5th, and Thursday, March 7th, at 5 P.M.; the Goulstonian Lectures will be given by Dr. Henry Head, F.R.S., on Tuesday, March 12th, Thursday, March 14th, and Tuesday, March 19th; the Lumleian Lectures will be given by Dr. J. F. Payne on Thursday, March 21st, Tuesday, March 26th, and Thursday, March 28th; while the Croonian Lectures will be given by Dr. W. D. Halliburton, F.R.S., on Tuesday, June 11th, Thursday, June 13th, Tuesday, June 18th, and Thursday, June 20th.

ISOLATION ACCOMMODATION AT COLCHESTER.

AN outbreak of diphtheria at Old Heath, a suburb of the borough of Colchester, has afforded opportunity for, or given rise to, a far from edifying discussion in the local press between Mr. Edgar Hunt, a medical practitioner, and Dr. George Brown, the medical officer of health of the borough. Other medical men have found themselves involved in the controversy and the general result is not, we fear, calculated to enhance the regard in which the medical profession is held in East Anglia. The correspondence, which occupies many columns of one of the local newspapers, can fortunately be briefly summarised. The isolation hospital, as far as we can judge from the several letters, is not up-to-date, and hence, among other things, it has been unable to cope with the demands recently made upon it. But this is not all. It is affirmed by Mr. Hunt that there is no proper disinfecting apparatus available, an allegation which in our view is sufficiently serious for a town of the size, importance, and obvious aspirations of Colchester. It is difficult to comprehend how a body of enlightened popular representatives, such as we imagine the members of the Colchester Corporation to be, should in these days regard it as consistent with their duties to leave their district without the modern facilities for isolation and disinfection. The treatment meted out to the patients at the fever hospital has been called in question, and this matter has perhaps unduly prolonged the correspondence above referred to. Mr. Hunt was anxious to obtain a written statement from the medical officer of health as to whether or not it was his practice to make use of diphtheria antitoxin at the hospital, and seeing that the destination of the reply was presumably to be the local newspaper the medical officer of health was not unnaturally averse to be thus catechised. There can hardly, we think, be any doubt in the minds of the medical profession in Colchester as to the great value of diphtheria antitoxin, especially when it is used early in an attack, and it is to be feared that the public debate which has taken place upon the subject in the press of Colchester may have produced a somewhat erroneous impression upon the minds of those who have followed the controversy. The pages of THE LANCET and the reports of the Metropolitan Asylums Board will afford a good estimate of the true position with regard to this remedy. Mr. Hunt is anxious for a Local Government Board inquiry into the outbreak of diphtheria, and presumably, also, into the administration of the hospital, but perhaps the exercise of a little common-sense and an adaptation to the necessities of the situation might obviate such a course. We see that references are made to the water-supply of the invaded areas in relation to the outbreak, but it may be well to point out that water-borne diphtheria is by no means a common occurrence, and that time might be better occupied in a house-to house inspection with a view to searching out and controlling cases of suspicious sore-throat. If the hospital staff and the accommodation are inadequate they should be promptly increased.

MALARIA AND MOSQUITOES.

AT a recent meeting of the Society of Arts at which Professor Ray Lankester presided, Major Ronald Ross, I.M.S., read a paper upon Malaria and Mosquitoes. After giving an account of the symptoms and course of malarial fever he proceeded to discuss the subject of prevention. Measures of prevention might be either public or private. The latter he would not discuss, but the former demanded examination on the ground of expense, for municipalities and the like authorities should not be required to spend money without there being a good prospect that the sums laid out would not be wasted. Koch's theory that mosquitoes should be let alone but that people should be cinchonised Major Ross considered as impossible to put into execution in a British colony, such as, for instance, Sierra Leone. The best method in his opinion was destruction or removal of the mosquito by means of surface drainage, cutting down undergrowth, and the use of various culicides. In our opinion Major Ross's ideas are very sound. The experiments of Sambon and Low seem to show that in Italy at all events immunity can be obtained by living in a mosquito-proof house between sunset and sunrise. They also apparently demonstrated the fact that the Italian mosquito does not bite during the day or possibly that the malaria-carrying variety only bites at night. But other experience would point to the fact that the extirpation of the mosquito would be the most effective measure of protection. In some countries mosquitoes bite viciously all through the day, as, for instance, in Lapland and in the Araxes valley. In the latter locality mosquitoes exist literally in millions, and are much more troublesome by day than by night. A medical man who travelled through this valley in 1884 was severely bitten during the day but only rarely, if at all, at night. Though he had never had any symptoms of malaria while away, some 18 months after his return, while hard-worked at a hospital, he developed sundry severe attacks of hæmoglobinuria, presumably due to malarial infection. A mosquito-proof house would have been no good in this instance, but a reduction in the number of mosquitoes would undoubtedly be of benefit.

THE DIFFERENCE BETWEEN A FRESH EGG AND A NEWLY-LAID EGG.

NINE times out of ten the trader, we fear, conveniently ignores the question of the difference between the newly-laid egg and the fresh egg, his concern being only to realise the best prices for his eggs, to which end he keeps them dubbed "new-laid" or "fresh" as long as he can before they become obviously "shop 'uns." A species of fraud is thus being commonly practised upon the public and it would be very satisfactory if some definition could be established which should sharply require the assortment of eggs into three classes, to be respectively known as "newly laid," "fresh," and "shop." A difficulty at once arises as to when an egg may fairly cease to be considered newly laid and when it has entered upon the "fresh" stage. There can be no doubt of the dietetic difference between an egg, say, one day old and another a week or more old. From the moment it is laid the egg, it is certain, undergoes definite changes of the precise nature of which we are ignorant, but which nevertheless affect the dietetic value of the contents. Eggs when kept, as is well known, gradually lose water by evaporation, and water is an essential constituent of the albuminous fluid. Indeed, the loss of water thus occurring is sufficient to make the egg lighter and on this a test has been established as a means of differentiation. A fresh egg, it is said, should sink at once in a 10 per cent salt solution, but the longer it has been kept the nearer the surface will it float. Perhaps by carefully studying this phenomenon we may be able to determine the exact age of an egg, and if once it is accepted that a newly-laid egg shall be an egg not more than 24 hours old some system of control over the sale of eggs "newly laid" as distinct from the "fresh" and "shop" descriptions might be inaugurated. Such an instrument, giving very exactly the density of an egg, might conveniently be called the "ooscope." Some attempt at guaranteeing the history of an egg has been made by branding upon it the date upon which it was laid, but obviously this method can hardly be relied upon. One thing is clear; there is an important difference between an egg that is newly laid and one that is comparatively speaking "fresh." One essential point is that a newly-laid egg when boiled is milky or creamy as regards the white part of it, whilst an egg commonly spoken of as fresh but which is not newly laid furnishes on cooking a white that is transparent or, more correctly, slightly opalescent. Many attempts have been made to preserve eggs in their newly-laid state, but such preserved eggs never satisfy this test of a newly-laid egg. The question is a very important one, especially at a time when eggs are scarce and when it is probable that fraud in regard to palming off fresh eggs as newly-laid eggs is practised with some frequency. The question is also important in relation to foreign competition, for undoubtedly foreign eggs which are imported into this country are often sold as newly-laid eggs. We cannot help thinking that home producers and the trade generally could if they chose usefully combine their energies and skill towards providing a means which would enable the public to obtain some guarantee that the egg purchased is really newly laid. Certain it is that persons would pay a high price for the really newly-laid egg rather than have an egg which could in no sense be regarded as newly laid thrust upon them at a lower price.

THE COLLECTION OF INFANTS' URINE AND FÆCES FOR ANALYSIS

IN the *Deutsche Medicinische Wochenschrift* of Oct. 18th Dr. B. Bendix and Dr. H. Finkelstein describe a contrivance which they have found very satisfactory for the separate collection of the urine and fæces of infants, when analyses have to be made, as in the course of investigations on tissue change Nearly five years ago Dr. Bendix introduced an arrangement for the same purpose which answered perfectly well provided that a constant watch over the movements of the infant was maintained both by night and by day.[1] Dr. Bendix and Dr. Finkelstein eventually employed a considerably modified arrangement which they have found to be perfectly reliable and which has the advantage of not requiring constant supervision. The child lies on a stout sheet which is stretched between the top and bottom rails of a cot and which is torn in half from the foot to the centre. The inner edge of each of these halves is turned outwards on itself and fastened to the outer border of the sheet, so as to make two hollow cones like legs of a pair of drawers tapering to a point. An ordinary woollen combination garment with the buttons in front is then stitched to the sheet, in such a way that the seam begins in the middle line at the level of the angle of the scapula and on coming to the small of the back it divides and is carried on each side to the back of the knee. The back opening of the woollen drawers must correspond exactly with the commencement of the division in the sheet, the legs being carried into the folded halves of the sheet already mentioned. When the infant is put into the combination garment the upper part of the body and the arms are quite at liberty and the child has also considerable freedom of motion for the legs. To prevent the gluteal region from slipping down and to make the whole arrangement steadier the under surface of the sheet as far as the small of the child's back is supported on pillows, so that the upper part of the body is always horizontal. A waist-belt, having a number of buttons and held up by braces, is also provided. The urine is caught by means of a glass vessel, in shape not unlike the glass "adapter" used in chemical laboratories. At one end it is large enough to receive the penis and scrotum and suddenly tapers to a small tube which passes into the neck of a bottle. The wide end is encircled by an indiarubber ring from which two indiarubber straps proceed in front and two behind, all four being buttoned to the waist-belt. The fæces are caught in a pan placed underneath the sheet. All the parts of the apparatus may be obtained from Mr. Ernst Lentz, 18, Birkenstrasse, Berlin.

THE CAPE OF GOOD HOPE COLONIAL BACTERIOLOGICAL INSTITUTE.

THE report of the Director of the Colonial Bacteriological Institute at the Cape of Good Hope for 1899 is full of interesting reading By far the greater portion of the report deals with the question of horse sickness, which is a perfect scourge to horses, asses, and mules in South Africa. Dr. A. Edington has succeeded, after a long series of experiments, in devising a protective method of inoculation, the technique and results of which are set out at length in the report, but as last week we were enabled to lay before our readers a paper upon the same subject by Dr. Edington we need refer no more to the subject here. Another matter referred to in the report is that very fatal disease amongst cattle—namely, redwater. A method of protection against this malady by means of a protective virus has also been devised by Dr. Edington and "continues to find favour with the stockholders in infected areas." Experiments have also been made with the "locust fungus" for the destruction of locusts with most gratifying results, but, unfortunately, the funds provided for the support of the five travelling instructors proved quite insufficient and they therefore had to be withdrawn Owing to farmers and others whose interests were involved carrying out the campaign of destruction in a half-hearted way the results have been much less successful since the withdrawal of the instructors. The institute supplied in addition vaccine lymph, diphtheria antitoxin, and sundry other viruses and vaccines for protection against "lung sick," anthrax, and the like. Bacteriological examinations into various pathological tissues, suspected milks, blood, and water were made to the number of 138.

"CONSUMPTION SANATORIA" IN SCOTLAND.

WE have just received the report for the year ending October, 1900, of "Consumption Sanatoria for Scotland." These homes are situate at the Bridge of Weir, Renfrewshire, and form a portion of the many philanthropic establishments inaugurated under the auspices of Mr. Quarrier. At present there is no accommodation save for women patients, and, as the report points out, there is sore need for a like establishment for men who are in general the bread-winners and whose illness therefore presses hardly upon their families. During the year with which the report deals there were 81 cases admitted and at the end of October, 1899, there were 25 patients remaining in the home, making a total of 106 Of these 66 were discharged after an average stay of 134 days, as compared with 56 discharged in 1899 after an average stay of 156 days, while 40 were under treatment at the end of October. The method of treatment adopted is that in vogue at similar institutions—namely, full diet, an open-air life, and strict personal supervision with attention to rest and exercise. The results, says the report, are very encouraging. Of 60 patients 12 are returned as "cured." This term, however, is only to be taken provisionally at present. Under the heading of "almost well" 17 patients are returned, 15 were "very much improved," 10 much improved, five "slightly improved," and in one the condition remains unchanged. Inquiries into the after-condition of patients since the opening of the establishment in 1896 show that 44 maintained the improvement, 13 relapsed, five were much worse, five were lost sight of, and 17 died. The report rightly urges upon both patients and medical men the necessity of applying for treatment at an early stage in the disease. The Scottish sanatoria are perhaps not so well known as they should be on this side of the border, and we are glad to be able to put on record the good work which it appears that the Bridge of Weir Homes are doing.

PAINTERS AND LEAD POISONING.

THE prevalence of lead poisoning among house painters and decorators is an old-standing evil, yet comparatively little has been done to mitigate it. In zinc there is to be found an excellent and a harmless substitute for lead, though it has not the "covering" power of lead; but it seems most difficult to break down trade customs and prejudices. In the manufacturing processes some improvements have been realised, the lead being now generally pulverised in closed receptacles so that the lead-dust does not fly about. Nevertheless, the cases of lead poisoning are still very frequent. In Paris the public authorities supply gratuitously sulphurous baths to all workers who manipulate lead. The expense which this occasions is more than compensated by the reduction in the number of days spent in the public hospitals by persons suffering from lead poisoning. But on the ground that prevention is better than cure the French painters recently held a congress which was attended by representatives of their trade in the principal towns of France. At this congress resolutions were carried denouncing the use of lead for the manufacture of paint and demanding that the law for compensation for accidents should be extended so as to apply to all cases of lead poisoning. So old is this grievance that in the reforming days which followed the revolution of 1848 a decree was promulgated by the French Government forbidding the use of carbonate of lead. Though this decree bears the date of August 24th, 1849, it has never been enforced. The Congress appointed a commission of five members to organise an agitation against lead paint and they held a first conference on Nov. 3rd last. The directors of two large Paris firms engaged in the manufacture of paint were present, as also was a representative of the Government, M. Alby, civil engineer. M. Finance, formerly a painter and now director of the Bureau of the Trade Associations at the Labour Office, contributed a paper full of statistics and technical information, setting forth the evils resulting from the use of lead and how easily zinc might be employed in its stead. Then the painters' delegates proceeded to interview the Minister of Public Works, asking him to enforce the decree of 1849, at least in regard to all work done for the State. The Minister gave a favourable reply and declared that henceforth only zinc should be employed in all State work. This was a good beginning and is an example which the British authorities might well follow. The representatives of the painters subsequently proceeded to the Ministry of Commerce and placed the resolutions which their congress had adopted in the hands of M. Millerand. The Minister replied that the Law on Accidents, though but recently enacted was still imperfect. It was nevertheless too soon to hope for its amendment. In the meanwhile, and in accord with his colleagues in the Ministry, he would do all that was necessary to enforce the decree of 1849 so that no more lead should be employed for the painting and decorating of State edifices. He hoped that the local authorities would follow the example given by the State, then it would only be necessary to persuade private employers to substitute zinc for lead. Thus it will be seen that this question has recently made good progress in France. We wish we could say as much in regard to Great Britain.

THE POISONING OF BEER IN MANCHESTER: A REPORT BY DR. NIVEN.

DR. J. NIVEN, the medical officer of health of Manchester, has presented a report to the hospital sub-committee dealing with the present outbreak of arsenical poisoning in Manchester. In his report he states that he first heard of the epidemic through Dr. E. S. Reynolds, who on Nov. 20th informed him that arsenic had been found in a sample of beer. At that time there was a large number of patients in the wards of the infirmary exhibiting a definite set of symptoms, and these patients, who had been admitted for some months previously, were all beer-drinkers drinking the cheaper kinds of beer. We shall publish the report in full next week.

ASEPTIC HAIRDRESSING.

WHETHER it be in the "Barber's Chair" in England or under the ministrations of the "*Figaro*" in Spain, hairdressing and shaving have always been associated with gossip and the exchange of ideas. But it is the rôle of the hygienist to step in and to indicate the evil consequences that may result from pleasant things. Even "*Figaro*," razor in hand, succeeds in "suggesting" Don Bartolo into a high state of fever; and the promiscuous use of razor, scissors, combs, and other implements by the hairdresser has on more than one occasion been denounced as a probable source of infection. Of course the better-class hairdressers are careful to keep all their instruments clean; but, as a rule, these are not cleaner than surgical instruments used to be before the days of antiseptic surgery. The question now arises whether a barber should not be as scrupulous in this respect as the operating surgeon. As barbers used to be surgeons they can only be flattered if to-day we draw their attention to the modern practices observed by surgeons. Nor is this a mere suggestion. The medical students and others of the Latin quarter in Paris have actually succeeded in conveying to hairdressers the lessons which they have learnt in the operating theatres of the hospitals. There are now several hairdressers in Paris who have adopted antiseptic methods. Nor does this occasion any particular trouble or expense. In front of each chair there is a gas-burner. Bone or celluloid combs are no longer employed; metallic combs are used instead. The barber turns on the gas, and before he commences operations he slowly passes his metallic comb several times through the flames. His scissors and razor are likewise thus purified by fire and his customer is reassured by witnessing this burning up of all the microbes before his hair is touched with the instruments. There remains, it is true, the brush which cannot be submitted to this fiery ordeal, but there is no risk of accidental cutting into the flesh with a brush. Also the risk from the brush is mitigated by the constant use of antiseptic hairwash in which thymol, on account of its pleasant odour, is the favourite ingredient. Thus have the principles of the operating-room been extended to the barber's shop, and it must be acknowledged that this is a distinct advance. The precautions may not be absolutely effective in every detail, still, they must tend to reduce very considerably whatever risk there may be. They are certainly characteristic of the times and of the influence that the discoveries of bacteriologists are exercising on our every-day life and habits.

"CERTIFICATION AND CLASSIFICATION OF DIARRHŒA DEATHS."

UNDER the above title a pamphlet has been reprinted from *Public Health* and issued by the Home Counties Branch of the Incorporated Society of Medical Officers of Health. It is published by Messrs. Rebman, Limited. It contains a paper entitled "A Plea for Uniformity in Classification of Diarrhœa Deaths," by Mr. Alfred Ashby, medical officer of health of Reading, in which he draws attention to the confusion arising from the present method of certifying and classifying deaths from "diarrhœa." The society above referred to before which the paper was read in April, 1898, appointed a committee of three of its members "for the purpose of taking steps to promote uniformity in classification of diarrhœa deaths." The committee, after an exhaustive inquiry, made two reports to the Home Counties Branch in April, 1899, and May, 1900, respectively. Acting on the recommendation of the Branch, the council of the society communicated with the Royal College of Physicians of London with a view to the appointment of a committee to deal with the question. The College appointed a committee the members of which issued a very valuable report in which they recognised the specific character of the disease generally termed "diarrhœa," assigned a definite name to it, and urged the entire disuse of its numerous other synonyms. We have already referred to this report in a leading article in THE LANCET of Feb. 3rd, 1900, page 320. The report is reprinted in the pamphlet now under consideration, together with the paper and reports already alluded to. The Home Counties Branch of the Incorporated Society of Medical Officers of Health deserves the thanks of the medical profession for the energy which it has shown in this matter. The conclusions arrived at by the Royal College of Physicians of London bear the stamp of authority, and it is therefore the duty of all practitioners to take note, in order that accurate statistics may be obtained of the prevalence of the disease in special places and at special times, and that due sanitary precautions may be taken to stay the spread of an epidemic.

DR. J. ANDREW TURNER, medical officer of health of Hertfordshire and medical officer of health of the combined districts of East Hertfordshire and Essex, has been appointed executive health officer to Bombay. Dr. Turner, when medical officer of health to the combined Leicester and Rutland districts, made a first-hand investigation in Paris into the antitoxin treatment of diphtheria for his sanitary authority, and his reports, which were published in THE LANCET of Nov. 17th (p. 1173) and Nov. 24th, 1894, (p. 1235), were the first reports on the treatment published in this country.

THE first Baillie Lecture was delivered in the school of St. George's Hospital by Dr. W. Howship Dickinson on Wednesday last, Dec. 5th, and the second will be delivered on Wednesday next, Dec. 12th, at 3 P.M. Dr. Dickinson is taking as his subject, "Considerations touching the Pathology and Relations of Diabetes."

DR. G. SEATON BUCHANAN has been instructed by the Local Government Board to watch the epidemic of neuritis alleged to be due to poisoned beer, and is now engaged in visiting various places which have been principally affected.

THE Right Honourable Sir Ford North, a retired justice of the High Court, is to conduct an inquiry into the management of the National Hospital for the Paralysed and Epileptic.

THE ROENTGEN RAY CASE AT HASTINGS.

THE recent case at Hastings, in which the Roentgen ray methods caused an injury preceding death, raises points of great practical importance to the medical profession as well as to non-medical operators with the rays and to the outside public. The following facts were deposed to before the coroner, Mr. Davenport Jones, at the adjourned inquiry held in the Hastings Town Hall on Nov. 17th. On March 21st last a widow lady, aged 68 years, met with an accident to her left hip while learning to ride the bicycle. She was taken to the local hospital where the opinion was expressed that no fracture existed. She was then removed home and was attended by Mr. Harry R. Mansell, who could not make up his mind at the moment that the hip was fractured. After watching the case for some time he thought that it would be advisable to clear up matters by applying the Roentgen rays. This was done, with the consent of the deceased, by a local photographer, Mr. J. H. Blomfield, on April 14th, when two exposures were made, according to the operator's statement, one of 35 and the other of 45 minutes, each hip being taken separately. The result was not considered altogether satisfactory by the local medical society which suggested that a further photograph to show both hips should be taken from the centre of the body. This was accordingly done with the consent of the deceased on April 27th by the same photographer with an exposure of 45 minutes. On both occasions Mr. Mansell attended and gave directions as to the position of the patient, but afterwards left the house and entrusted further details to the photographer. On the first occasion, according to the last-mentioned, the part of the body exposed was covered with clothing, but on the second it was bare. On May 4th an eruption developed on the left lower abdominal region. This was recognised by Mr. Mansell as an x ray injury and was treated with ointment, but the dermatitis developed into an ulcerated surface of the size of the hand. On July 5th the deceased declined further attendance from Mr. Mansell and called in Dr. J. H. Roberts. The latter brought Mr. A. R. Ticehurst in consultation, and attended the deceased until her death on Nov. 5th. On July 7th Dr. Roberts found her to be suffering from a sloughing wound about seven inches by three and a quarter inches. Death, in his opinion, was caused by exhaustion from the effects of shock which resulted from two injuries, the fracture of the thigh and the action of the Roentgen rays. Mr. Ticehurst, who visited the deceased in consultation and who subsequently performed a post-mortem examination, stated that when he saw the deceased alive on Oct. 5th he found her to be suffering from a dry sloughing wound of the abdomen. At the necropsy the wound had lost its slough, but there was little sign of repair. There was little fat about the body, the heart was flabby, the stomach was empty, the liver showed signs of old mischief, the vessels were degenerated, and he found an impacted intra-capsular fracture of the neck of the femur. Mr. Ticehurst would not say that the condition of the body would be sufficient to cause death apart from the wound. The niece of the deceased stated that her aunt's mind gave way several weeks before her death and she refused food, which had to be forced upon her by the nurses. The photographer, Mr. Blomfield, stated that he had had four or five years' experience with the rays, part of the time at the Hastings Hospital, and had met with no injurious effects from similar prolonged exposures. Dr. Lewis Jones, in charge of the electrical department of St. Bartholomew's Hospital, gave evidence to the effect that he had seen the apparatus used by Mr. Blomfield to take the photograph of deceased. There being no rash between the first and second exposures he would consider a medical man right in assuming that the patient was not sensitive to the rays. The risk of an x ray burn was always present in long exposures. The apparatus used by Mr. Blomfield was a year and a half out of date. In default of a better instrument the one used was a proper one. It gave a 10 inch spark and a similar one was in use at St. Bartholomew's Hospital until a year and a half ago. He himself had given exposures of 40 minutes, but the usual length of time was seven or eight minutes. Short exposures were less likely to cause burns than long. At the time when the photograph was taken Mr. Blomfield's coil was working at five and a half inches. The coroner summed up and the jury returned a unanimous verdict: "That the deceased met her death from shock and exhaustion following the accident and the effects of the Roentgen rays upon a weakened system. No blame attached to either the medical man or the photographer."

With regard to this case it may be remarked that the fact that the friends of the deceased not having been represented by expert evidence detracts somewhat from the value of the inquiry. It was admitted that no note was made of the time of the exposure, the distance of the tube from the plate, and other details that cannot safely be left to the memory. From the evidence it is clear that a burn resulted from prolonged exposure to the focus-tube, probably from the third exposure of 45 minutes on April 27th, as the rash appeared seven days after that date. However, the fact that the first exposures were not followed by dermatitis during the 13 days that elapsed does not absolve those exposures from all blame. It is reasonable to assume that the degenerative changes in the body of the deceased were indirect factors in the causation of the burn just as they were in the fracture of the hip. Unfortunately, for reasons already stated, the full details of the exposures are not available. At the same time we are told of one important differing condition of experiment—namely, that the surface of the body was not protected by clothing on the third exposure, the one from which the damage in all probability resulted. No mention was made of the crucial point of the distance of the focus-tube from the skin. Nor was the fact made clear to the court that a 10-inch coil working at five and a half inches is reduced almost, if not quite, to the lesser value. The bearing of this upon the length of exposure is obvious. With his coil working at 10 inches Mr. Blomfield could have almost halved his exposures, and the focus-tube burn is distinctly related to the length of exposure. The reasons for a coil not working up to its full strength are various, but all are open to remedy. The mention of these facts will show the desirability of having expert evidence on both sides of so highly technical an inquiry. As regards the responsibility of a medical man who engages a non-medical man to take a Roentgen photograph the matter is not advanced by this case. The fact that the patient consents to the photography can hardly absolve the medical attendant. If the latter hands over the operation to a non medical man it is a question how far he is relieved of responsibility. A chemist is responsible for errors in dispensing a prescription, but he is licensed to practise pharmacy, whereas the electrical or photographic worker with the rays has no such recognised and tested legal status. If the non-medical photographer had undertaken the case for the local hospital what would have been the position of the committee of that institution in the matter? On the other hand, the employment of a medical Roentgen ray expert would clearly absolve a medical man of further responsibility. Any medical operator must have hesitated to expose to the rays for 45 minutes an old lady who had been laid up for five or six weeks with a broken hip. It seems undesirable, moreover, that female patients should be submitted to the manipulation of instrument-makers and other non-medical workers with the rays. The moral of the case appears to be that apparatus should be up to date and that medical men will act wisely in sending their cases to medical Roentgen ray experts, of whom there are a fair number available.

HOSPITAL ABUSE IN CONTINENTAL TOWNS.

AT a meeting of the Charity Organisation Society held at the Royal United Service Institution on Dec. 3rd Mr. H. NELSON HARDY, F.R.C.S. Edin., read a paper on the above subject. He stated that at one of the scientific congresses held in Paris during the Exhibition this year Dr. Thiéry, professor in the Paris School of Medicine and surgeon to one of the Paris hospitals, had read a paper on behalf of the Syndicate of Medical Men of the Seine, in which a number of facts and recommendations dealing with hospital abuse were brought forward to which it was desired to give a wider publicity. Discussing first the question as to who should be considered the sick poor, it was pointed out that in Paris the difficulty was greater than in the provinces, since between the very poor and the very rich, about neither of whom can there be any question, there is a middle class consisting of mechanics and clerks on small salaries worse off than the average clerk in England, and of employés, to whom gratuitous assistance might rightly be given in serious cases requiring treatment as in-patients. With regard to workmen suffering from trade accidents, as these are mostly provided for by insurance and in any case the expense falls not on the workman but on the employer of labour, the case ceases to be a necessitous one and should be paid for. Examples were given of hospital abuse. The cases were mentioned of a rich gentleman who drove his daughter to the Charité Hospital in his own carriage to have her treated for hip disease, of a jockey earning 20,000 francs a year applying for advice for a sprain, and of a lady who incurred the expense of travelling from America for advice and who applied at the Pitié for gratuitous treatment. The maternity cases in Paris which are attended gratuitously amount to 18,000, or one-third of the total births. 8000 of these are treated in the lying-in hospitals and 10,000 by midwives. Sunday consultations at the hospitals had been established but had not been well attended by the working-classes, the Paris working-man preferring to lose a day's work rather than a few of his hours of idleness on Sunday. Having given the results of inquiries in provincial towns in France, as well as at Brussels, Berlin, Copenhagen, Vienna, Gothenburg, and Heidelburg, the author considered proposals for reform. The part-payment system was condemned, and the proposed suppression of the out-patient department was thought too drastic. A system of inquiry into the means of applicants was suggested to be carried out by specially appointed officers under the control of one of the medical officers of the hospital.

On the invitation of the Chairman, Mr. T. HOLMES, F.R.C.S. Eng., the discussion which followed was opened by Dr. W. KNOWSLEY SIBLEY, who referred to the bribery which existed with regard to nursing in the Paris hospitals. This did not exist in England, he was glad to say, though in the out-patient department porters were known to receive "tips" for getting a patient seen by the medical officer out of his or her turn. He pointed out that in Paris patients who sought free treatment at the hospitals were obliged to attend a particular hospital in the district in which they lived. Some supervision was therefore possible and abuse could not take place to the same extent as it did in England where a person in the north of London could attend a hospital in the south and *vice versâ*. He advocated as a remedial measure for hospital abuse the formation of a central hospital board.

Dr. H. SELFE BENNETT said that the Charity Organisation Society had taken up the matter because it was sapping the morals of the community generally and also pauperising it. But little good would be done till the hospitals took more interest in the matter. He thought that it was a scandal that a hospital must be in difficulties before the public would subscribe to it.

Mr. HOWARD endorsed Dr. Bennett's views and expressed himself in favour of a central hospital board.

Mr. HOLMES, referring to some remarks from Dr. Sibley to the effect that Mr. Hardy's paper could not refer to the Paris hospitals generally, said that until Dr. Thiéry's facts had received some authoritative denial he must accept them as depicting the actual state of things which existed. He expressed the view that to put a hospital under a municipal body was sure to lead to its deterioration. Perfect efficiency was best secured by perfect freedom. Mr. Hardy's paper was principally directed to the pecuniary part of the question of abuse, but he (Mr. Holmes) believed that very few people would go through the many discomforts that were required to gain admission in a hospital if money were no object to them. A much more important question was that of efficiency. It was a matter of far more importance than whether a man who earned £2 a week got into a hospital or not. The pecuniary test was quite an illusive one. A man who earned 30*s*. per week with two children was much better off than a man who earned £2 10*s*. with 10 children. The worst feature of the out-patient department was that they undertook to do what was physically impossible. Patients were seen at the rate of about 100 seconds each. Mr. HARDY briefly replied, and a vote of thanks to the reader of the paper concluded the proceedings.

"THE INACCURACY OF THE MEDICAL REGISTER."

A LEADING article in THE LANCET of Oct. 27th showed the Medical Register to be an inaccurate compilation, though it made no attempt to show the measure of that inaccuracy. As a result of our remarks the following report has been made to the Executive Committee of the General Medical Council:—

REPORT TO THE EXECUTIVE COMMITTEE BY THE REGISTRAR ON THE MEDICAL REGISTER.

By the direction of the President of the Council I have to report on some alleged inaccuracies in the Medical Register to which attention was drawn by an article in THE LANCET on Oct. 27th. The article dealt with two questions: (1) the appearance on the Register of the names of practitioners who were dead; and (2) the vagueness of some of the addresses. A list was given of 35 practitioners who were dead but whose names still appear. An analysis of this shows that three of these have been removed during this year, and that 14 belong to the Scotch or the Irish Branch. With these latter I have no official right to deal, and the Registrars in Scotland and Ireland respectively are fully alive to their duties in correcting the Register. Deducting these 17 names, there remain 18 respecting which some explanation is required from me. The committee will remember that steps are being taken in this office to send circular letters of inquiry, under Section 14 of the Act, to all persons on the English Register, to ensure its accuracy before the election of Direct Representatives to take place next year. A great part of this work has been done, but a section of some 7000 or 8000 names remains to be dealt with next spring. Within this section 10 of the 18 names referred to occur, and these will all be duly dealt with next year under the operation of Section 14. There remain eight names to be accounted for. Three of these are those of practitioners who died in Australia and of whose deaths it was extremely difficult to obtain any information, as there are no local registrars abroad whose duty it is under the Medical Acts to report deaths. Five names of practitioners which are stated by the writer in THE LANCET to be dead remain to be referred to. I use the word "stated" with no desire to call in question the accuracy of the information possessed by THE LANCET, but to remind the committee that your officials here cannot act except on legal evidence. We make every use we can of obituary lists, carefully looking through them and sending letters of inquiry in the case of every death that we hear of unreported by a local registrar, but we must have either a returned letter or a death certificate before erasing a name, or we must wait for six months after sending the letter. I should be glad to simplify the work of the office by at once striking off the Register the names of all practitioners whose deaths are reported by the medical press in this country or abroad, but without the direction of the Council I should be acting very wrongly in doing so. The committee will perhaps allow me to refer briefly to some of the causes which conduce to the non-erasure *from the Register of the names of deceased* practitioners. The proximate cause is of course that the deaths are not reported by the local registrars, whose duty it is to report them, but there are more remote causes. Why are they unreported? Not always, or mainly, I think, because the local registrars are negligent in performing their duty in this respect, for the discharge of which they, moreover, receive a fee; but because often they are not aware that the deceased person was a medical man whose death ought to be reported. When a practitioner, either on account of advanced age or some other cause, has ceased to practise, and retired, possibly into a new neighbourhood, he ceases to be known as a medical practitioner, and when his death occurs he is regarded as a private individual, and no certificate from the local registrar is therefore forwarded to this office. In other cases young men—and unfortunately the percentage of deaths among newly-registered practitioners is very high—travel into distant parts in search of health, and some dying, chiefly among strangers, are unknown to have been medical practitioners. There is yet another class of men who change their profession. I have myself known several medical men who have become clergymen, and others doubtless enter other professions in the same way, and naturally when their deaths occur they are returned to the local registrar as of that profession to which they last belonged.

Thus there must always be a certain number of deaths unreported by local registrars, and it is only by continuing the plan lately *adopted in the office of systematically* sending out letters to all persons on the Register under Section 14, that the names can be removed.

The second subject referred to in THE LANCET was that of the vagueness of some addresses, and the names of eight practitioners were given whose only address was "Australia." On this point I would remark that great care is taken to obtain from a person registering for the first time a sufficiently full address, and I do not know of any case in which such a vague address has been accepted, though *in* the unlikely event of the practitioner insisting upon its acceptance, I do not quite see how it could be refused. The vague addresses, however, come about afterwards, and I will explain how. A practitioner decides to go abroad, and just before he leaves his old home, or perhaps afterwards when travelling—for we have sometimes had letters written on board ship—he bethinks himself to tell us that the old address is no longer his, and that he is going abroad, say, to Australia. Well, on receipt of this intimation the old address manifestly cannot be retained, *we have been plainly told* that it is incorrect, and for the time being "Australia" is put against the name in lieu of anything better, and we await the subsequent arrival of more detailed information. In many cases this information comes when the practitioner has fixed upon his domicile, but sometimes, either because he forgets to write or does not think it worth his while, no further advice comes, and the address of Australia, used temporarily, has to become permanent.

With the committee's permission *I should like to refer very* briefly to another letter that was a sort of addendum to the previous article. It appeared in the issue of THE LANCET of Nov. 17th, and was from a Mr. Taaffe of Londonderry who, under the heading of "The Inaccuracy of the Medical Register," gave a list of five names of persons known by him to have died in that neighbourhood, though the names still appeared. Now investigation showed that these practitioners certainly were dead, but investigation also showed that they were all living at the time that the Medical Register left the office for press and that they died subsequently during the present year and were all duly taken off. I was advised of the death of one of them in February, of that of another in March, of a third in May, of a fourth in July, while the fifth practitioner died on Nov. 8th, just nine days before the letter of complaint appeared. It is difficult to conceive of a more groundless letter of complaint, but unfortunately it was unwittingly assumed by THE LANCET that the letter contained a just charge, and an editorial note was subjoined pointing out that the letter "*added force*" *to the view* that the Medical Register was "dangerously inaccurate," and courteously reminding the Medical Council that it would be well if it discharged its duties better.

The Medical Register may, of course, have its blemishes, but it ought to be remembered that it contains over 35,000 names of practitioners scattered over the whole world, in regard to some of whom it is extremely difficult to obtain official information, so that while, for the reasons *I have pointed out, it is* scarcely possible to avoid the appearance of the names of a few practitioners who are dead, the general accuracy of the Register is, considering this difficulty, well maintained, and the value of the work is, I would humbly submit, greater than is supposed by many.

Nov. 26th, 1900. HENRY E. ALLEN, Registrar.

We cannot altogether congratulate the General Medical Council or the Registrar upon this report. We showed that the Register contained the names of at least 35 dead persons (we have reason to know that the list could have been very much extended), several of whom had been dead for some years. Mr. Allen's report deals with these 35 in the following way. Three of the names, he says, have been removed this year. Possibly; but why were they not removed before? Which three are they and how long have their late owners been dead? With 17 names he says he has no official right to deal, the matter being in the hands of the Registrars of Scotland and Ireland. Possibly again, though in another part of his report he does deal with Irish names; but we presume the Executive Committee of the General Medical Council desired the whole matter to be gone into when they gave Mr. Allen his instructions. Either the Executive Committee gave the wrong instructions, or they intended Mr. Allen to furnish them with full information, or they do not desire to have a full answer published. Of the 18 names remaining Mr. Allen says that 10 are going to be dealt with next year. So we have done some good in ventilating the inaccuracy of the Medical Register. The other eight names give Mr. Allen more trouble than they need. Surely the sending of eight registered letters in accordance with the Act will settle the question whether they should remain on the Register or not.

Mr. Allen then refers generally to the causes which conduce to the inaccuracy of the official roll of the medical profession. Here he makes out a good case for the difficulty of his office. We are perfectly aware that the General Medical Council must have legal proof of a man's death before erasing his name, and have never even faintly suggested that an obituary notice in our columns should be taken as a proof of death. But the announcement of a man's death in the papers has more than a casual relation to his death. Such announcements are more often true than not—such, at least, is our journalistic experience. We think that when a man's death is announced in the press, and when, after the lapse of some reasonable time, no legal notice of the death reaches the Registrar, he might despatch a registered letter to the last address in the Register in accordance with the Act. However, the machinery of the Registrar's office is not our business. Mr. Allen says that the names of dead men remain on the Register because the local registrars of deaths do not send the necessary information to the Registrar, and he suggests that their omission is due to the fact that the deceased medical men have retired from or changed their profession. The number of medical men who change their profession is so small as not to be worth considering out of 35,000 persons, and the number who retire from practice so completely that their past calling is unknown is probably smaller.

We are glad to have obtained an explanation of how so vague an address as "Australia" comes to find a place as a registered address. We do not quite understand how it is that the *addresses of "India" or "Canada"* or "America" have not also been accepted as sufficient in analogous cases; but perhaps they have and have escaped unnoticed. The remedy is so obvious that we are sure that Mr. Allen and the Executive Committee of the General Medical Council have already given the necessary directions. If the practitioner *does not send his address his name must* be taken off the Register. Such entries as "Mr. J. Smith, America," "Mr. T. Jones, South Africa," invite personation and are a source of danger to the public.

Mr. Allen says that Mr. Taaffe's letter was an addendum to our article. It was not. But we own that we mistook Mr. Taaffe's meaning. We are glad that the names of the dead men which Mr. Taaffe mentioned have been removed from the Register, but if Mr. Allen can produce this information why cannot he produce information concerning other dead Irishmen who still live in the official roll of their profession?

We courteously repeat that it would be well if the General Medical Council gave the profession a more accurate Register. We do this without being in the least blind to the energy of the Registrar or to the arduous nature of his task. But the Register is dangerously incorrect, and it is our duty to point this out until improvement under some systematic method of emendation has taken place. We shall watch next year's issue with interest.

ASYLUM REPORTS.

London County Asylum, Banstead (Annual Report for 1899).—The average number of patients resident during the year was 2436, and comprised 1069 males and 1367 females. During the year 441 patients were admitted, 261 being males and 180 females. Of these 83—viz., 36 males and 47 females—were not first admissions. Dr. T. C. Shaw, the medical superintendent, states in his report that in many of the cases there were few symptoms of insanity present on admission; these were mostly alcoholic cases "which would have been better detained at the workhouse a short time longer and then discharged. The form of disease was not of a very excited type." Many cases of general paralysis among the admissions were of the demented type. Among the causes of insanity in the admissions drink was an etiological factor in 18 per cent. of cases, hereditary taint was acknowledged in 15 per cent., while the existence of previous attacks was shown in 23 per cent. All these numbers were probably below the truth. During the year 170 patients (94 males and 76 females) were discharged as recovered, or 6·9 per cent. of the average number resident. The deaths during the year amounted to 196—viz., 129 males and 67 females, or 8·0 per cent., as calculated on the same basis. During the year 112 post-mortem examinations were made. It is believed that improvement in the system of heating the building during the night has caused a material improvement in the hygiene of the asylum community. Among the deaths during the year 2 were due to Bright's disease, 6 to senile decay, 12 to cerebral apoplexy, 13 to cardiac and valvular disease, 18 to epilepsy and chronic cerebral disease, 21 to bronchitis and pneumonia, 24 to phthisis, 38 to general paralysis of the insane, and 51 to chronic brain wasting. In one case of death due to fracture of the sternum an inquest was held and an inquiry into the circumstances was made by the Commissioners in Lunacy, but no light could be thrown as to the manner in which this casualty was sustained. Dr. Shaw refers to the question of the separate treatment of phthisical patients and to a special report made by him to the Asylums Committee. A nurse and a male attendant died from phthisis. Five patients escaped from the asylum and four of these were brought back shortly after. With the exception of influenza there has been no outbreak of disease during the year. The Lunacy Commissioners in their report advert to the fact that no seclusion has been resorted to during the year preceding their visit and in only one case has mechanical restraint been adopted. The case-books and the medical records generally are adequately kept. "The record of service is very satisfactory. However, nine attendants were, since the last visit, dismissed for misconduct, and three of each sex were allowed to resign to escape dismissal." The wards were generally found very clean and bright. The Commissioners urge the provision of a laundry for foul linen which has long been needed and which constitutes a want that should certainly be supplied. The asylum sub-committee state in their report that the profit realised on the farm during the year amounted to £464 6*s.* A water-softening plant has been put down and is in operation. 24 employés of the asylum were serving with the colours in South Africa and allowances not exceeding half pay have been granted in 16 cases. Building, repairs, additions, and alterations have been made during the year at a total cost of about £8932.

Suffolk County Asylum (Annual Report for 1899).—The average number of patients resident during the year was 605 and comprised 266 males and 339 females. During the year the admissions amounted to 196—viz., 93 males and 103 females. Of these 10 males and 9 females were not first admissions. Dr. James R. Whitwell, the medical superintendent, points out in his report that there were 15 patients at the end of the year belonging to the county more than at the beginning, that this, as in the case of the annual increase of the previous year, was "in excess of the average usually considered to be normal to this asylum," and would probably necessitate boarding out at an early date. A considerable proportion of the admissions were found to be in a condition of serious physical ill-health "owing to the regrettable tendency to retain patients suffering from acute mental disease at home." A considerable number of the admissions were of the aged, chronic, and harmless class to whom asylum treatment could be of no service, and whose removal from workhouse to asylum meant a very considerable increase of maintenance—expense to ratepayers without any corresponding advantage. A certain number of out-patients continued to come from time to time for advice or treatment, chiefly from the union districts nearer to the asylum. Some of these have made good recoveries, while others have required re-admission. During the year 71 patients—viz., 35 males and 36 females—were discharged as recovered, or 11·7 per cent. of the average number resident. The deaths amounted to 70—viz., 36 males and 34 females—or 11·5 per cent., as calculated on the same basis. Of the deaths two were due to epilepsy, two to bronchitis, six to tuberculosis, six to senile decay, eight to general paralysis of the insane, 13 to chronic Bright's disease, and 19 to cardiac and valvular diseases. Post-mortem examination was made in every case with the exception of one. Inquests were held by the coroner in the case of one male and one female patient, who died somewhat suddenly, but from natural causes. The only serious casualty was the case of a male patient who, while out on trial, committed suicide by throwing himself in front of a train in motion. Great efforts have been made to keep as many patients as possible usefully occupied or employed both for their own good and as a source of economy. Thus 73 per cent. of male and 87 per cent. of female patients were employed in farm, garden, needlework, laundry, and otherwise. New farm-buildings are being erected to accommodate a larger number of cows, as the milk-supply has proved insufficient. The water-supply was satisfactory, but the same could not be said of the gas, which, however, will soon be superseded by the electric light. The cost of maintenance has risen somewhat during the year owing to a variety of causes, including increased price of goods, increase of the staff of nurses and attendants, the necessity of keeping vacancies in the asylum, and boarding-out of patients. The Lunacy Commissioners in their report state that all floors are now cleaned by dry rubbing, that the surroundings of the patients have been ameliorated, and that it is proposed to dispose of the sewage in future by Dibdin's system of bacterial tanks. It has been decided to increase the accommodation of the asylum by 280 beds and not to build a second asylum in another part of the county. The case books and post-mortem records are kept carefully and intelligently.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 5947 births and 4017 deaths were registered during the week ending Dec. 1st. The annual rate of mortality in these towns, which had been 16 9, 17·6, and 17·6 per 1000 in the three preceding weeks, further rose to 18·0 last week. In London the death-rate was equal to 17·9 per 1000, while it averaged 18·2 in the 32 large provincial towns. The lowest death-rates in these towns were 9·1 in Croydon, 12·3 in Cardiff and in Norwich, 13 8 in West Ham, and 14·5 in Blackburn; the highest rates were 21·5 in Wolverhampton, 22·8 in Halifax, 22·9 in Liverpool, and 26·9 in Sunderland. The 4017 deaths in these towns included 356 which were referred to the principal zymotic diseases, against numbers decreasing from 485 to 351 in the five preceding weeks; of these, 89 resulted from diphtheria, 71 from measles, 71 from whooping-cough, 55 from "fever" (principally enteric), 42 from diarrhœa, 27 from scarlet fever, and one from small-pox. No death from any of these diseases occurred last week in Norwich; in the other towns they caused the lowest death-rates in Croydon, Plymouth, Birkenhead, and Gateshead, and the highest rates in Swansea, Wolverhampton, Derby, Blackburn, and Sunderland. The greatest proportional mortality from measles occurred in Wolverhampton and Swansea; from scarlet fever in Blackburn, and Sunderland; from whooping-cough in Huddersfield, Blackburn, Sunderland, Hull, and Derby; and from diarrhœa in Wolverhampton and Blackburn. The mortality from "fever" showed no marked excess in any of the large towns. The 89 deaths from diphtheria included 29 in London, eight in Sheffield, seven in Leeds, and six in Leicester. One fatal case of small-pox was registered last week in London, but not one in any other of the 33 large towns; two small-pox patients remained under treatment in the Metropolitan Asylums hospitals on Saturday last, Dec. 1st, but no new case was admitted during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2727, against 2728 and 2725 in the two preceding weeks; 279 new cases were admitted during the week, against 289, 261, and 246 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 352 and 322 in the two preceding weeks, rose again last week to 436, and were seven above the corrected average. The causes of 46, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Manchester, Bradford, and 10 other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Newcastle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2, 19·9, and 20·3 per 1000 in the three preceding weeks, further rose to 21·7 during the week ending Dec. 1st, and showed an excess of 3·7 per 1000 over the mean death-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·8 in Perth and 17·2 in Leith to 25·2 in Paisley and 26·6 in Greenock. The 672 deaths in these towns included 42 which were referred to whooping-cough, 19 to diarrhœa, 12 to measles, six to diphtheria, five to scarlet fever, four to "fever," and one to small-pox. In all, 89 deaths resulted from these principal zymotic diseases, against 75 and 69 in the two preceding weeks. These 89 deaths were equal to an annual rate of 2·9 per 1000, which was 1·3 above the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had increased from 13 to 35 in the seven preceding weeks, further rose last week to 42, of which 33 occurred in Glasgow, five in Greenock, and two in Edinburgh. The deaths from diarrhœa, which had been 16 and 20 in the two preceding weeks, declined again to 19 last week, and included six in Glasgow, six in Dundee, and four in Edinburgh. The fatal cases of measles, which had been 13 and eight in the two preceding weeks, rose again last week to 12, of which seven were registered in Aberdeen and four in Edinburgh. The deaths from diphtheria, which had been 11 and four in the two preceding weeks, increased to six last week and included two in Glasgow and two in Aberdeen. The fatal cases of scarlet fever, which had been four and five in the two preceding weeks, were again five last week, of which four occurred in Glasgow. The deaths referred to different forms of "fever," which had declined from 12 to six in the four preceding weeks, further fell to four last week, and included two in Glasgow and two in Paisley. The fatal case of small-pox was registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 163 and 156 in the two preceding weeks, rose again last week to 160, and were 29 above the number in the corresponding period of last year. The causes of 35, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·0 and 26·1 per 1000 in the two preceding weeks, declined again to 24·5 during the week ending Dec. 1st. During the past four weeks the death-rate in the city has averaged 24·8 per 1000, the rate during the same period being 17·3 in London and 18·8 in Edinburgh. The 164 deaths belonging to Dublin registered during the week under notice were 11 less than the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 11 and 19 in the two preceding weeks; of these, six resulted from whooping-cough, three from "fever," one from diphtheria, and one from diarrhœa. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·4 in London and 1·9 in Edinburgh. The deaths from whooping-cough, which had increased from one to five in the three preceding weeks, further rose last week to six. The fatal cases of "fever," which had been three and eight in the two preceding weeks, declined again to three last week. The 164 deaths in Dublin last week included 29 of infants under one year of age and 41 of persons aged upwards of 60 years; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number in the preceding week. Four inquest cases and two deaths from violence were registered, and 57, or more than a third, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Staff Surgeon Herbert Parke Shuttleworth has been placed on the retired list of his rank.

Surgeon A. S. G. Bell is appointed to the *Boscawen* for the *Minotaur*.

ROYAL ARMY MEDICAL CORPS.

Captain C. B. Lawson has arrived at Dover for duty and has been posted to the Station Hospital, Western Heights. Major H. J. M'Laughlin has assumed medical charge of troops, Station Hospital, Glencorse, vice Lieutenant-Colonel A. L. Brown, A.M.S. (r.p.). Captain A. W. N. Bowen has been ordered to proceed from Calcutta to Darjeeling to assume temporary medical charge of the Station Hospital, vice Lieutenant-Colonel J. Watson. Captain E. W. Bliss has assumed medical charge of the Small Arms Ammunition Factory and the Departmental Followers' Hospital, Dum Dum, the Foundry and Shell Factory, Cossipur, and the Powder Magazine Dispensary, Dackinsore.

MILITIA MEDICAL STAFF CORPS.

Major Sir James Richardson Andrew Clark, Bart., late Army Medical Staff, to be Surgeon-Lieutenant-Colonel.

VOLUNTEER CORPS.

Artillery: 1st Cheshire and Carnarvonshire: Surgeon-Lieutenant R. B. Wright to be Surgeon-Captain. 5th (Irish) Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Major D. E. Flinn to be Surgeon-Lieutenant-Colonel. *Rifle:* 1st Volunteer Battalion the Worcestershire Regiment: Bertram Addenbrooke to be Surgeon-Lieutenant. 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Lieutenant H. H. S. Scott resigns his commission; Surgeon-Captain A. Macphee to be Surgeon-Major. 1st Cinque Ports: Henry George Lynwood Allford to be Surgeon-Lieutenant.

MENTIONED IN DESPATCHES.

In the despatches received by the Secretary of State for the Colonies from the Governor of the Gold Coast, Sir F. M. Hodgson, K.C.M.G., the names of Dr. McDowell, Principal Medical Officer to the Field Force, and Assistant Colonial Surgeons P. J. Garland, E. H. Tweedy, and A. J. Chalmers are mentioned for their help, zeal, and energy; Dr. Tichborne, West African Frontier Force; Mr. K. F. T. Buee, Gold Coast Service; Dr. Langstaff, Gold Coast Service; Surgeon-Lieutenant Fletcher, Militia Medical Staff Corps, wounded; Dr. MacFarlane, Lagos Hausas, wounded; and Dr. De Groot, Gold Coast Service, are also referred to and Colonial Surgeon Hay is mentioned as one of the officers selected to guard the Fort at Kumassi. "The mental anxiety which these officers [those in charge of the Fort] had to endure," says the despatch, "must have been very severe, and as each day passed and brought them and the gallant soldiers under their command nearer to the end the strain upon them must have become almost unbearable. For three weeks they truly and unflinchingly upheld the honour of the British flag under circumstances which might have appalled the stoutest heart."

TRANSVAAL WAR NOTES.

In a despatch from Lord Kitchener dated Bloemfontein, Dec. 1st, and dealing with General Paget's engagement, among the list of killed and wounded are the names of Lieutenant Challis, Royal Army Medical Corps, who was severely wounded, being hit in three places while gallantly attending wounded men under a heavy fire, and Surgeon-Captain Godfray, New Zealand Mounted Rifles.

Major T. Archer, R A.M.C., Lieutenant F. S. Walker, R.A.M.C., and Civil Surgeon D. V. M. Adams have arrived in England, invalided, in the P. and O. transport *Assaye*. Lieutenant W. Jagger, R.A.M.C., and Civil Surgeons W. L. Wainwright, L. V. Cargill, and W. C. Allan also arrived in the same vessel, having been in medical charge of the ship.

The Princess of Wales has forwarded from Sandringham 15 brace of pheasants for the patients at the Gables Military Convalescent Hospital, Surbiton, which Mr. Alfred Cooper founded and is maintaining during the war.

Lieutenant-Colonel H. L. Battersby, R.A.M.C., and Civil Surgeons J. A. Barnes, L. Cooper, and J. E. Ker are in medical charge of the *Orotava* which left for England on Nov. 28th.

Civil Surgeon A. E. Elliott died at Middelburg on Dec. 1st and Civil Surgeon C. C. Parsons at Harrismith on Dec. 2nd, both from enteric fever.

VOLUNTEER OFFICERS' DECORATION.

This decoration has been conferred upon Surgeon-Major F. W. Gibbon of the 1st Durham Royal Engineers (Volunteers).

VOLUNTEER MEDICAL STAFF CORPS.

The annual supper and smoking concert of No. 1 Company, composed of students from University College Hospital, King's College Hosiptal, the Middlesex Hospital, and Charing-cross Hospital, took place at the Headquarters, Calthorpe-street, on Nov. 30th. About 70 were present, Surgeon-Captain Whait, commanding No. 1 Company, being in the chair. Among the toasts were "The Queen," "The Guests," and "Those of Our Corps Serving in South Africa." Speeches were made by the commanding officer, the major, and the adjutant. The concert was a great success and an altogether enjoyable evening was spent. The guests included Surgeon-Lieutenant-Colonel Squires, V.D., Major Matthews, Captain Wray, R.A.M.C., Surgeon-Captain Macgregor (19th Middlesex), and other officers of the Volunteer Medical Staff Corps, together with Sergeants Tytheridge and Turtle, of the Imperial Yeomanry Hospital; and two members of the City Imperial Volunteers.

LORD ROBERTS'S FAREWELL ORDER.

There has probably never before been such a farewell order addressed by a general to his army as that which Lord Roberts has addressed to the forces lately acting under his command in South Africa. If the campaign in that country has been in many respects unique in the history of modern warfare so has the order which it has occasioned. It has throughout a true ring and expresses the real mind of a distinguished commander who is unaffectedly proud of his army and profoundly appreciative of the labours which it has undergone, of the courage and cheerfulness by which it has been sustained, and of the qualities of humanity and forbearance which the troops have exhibited throughout one of the most arduous and trying campaigns on record. As we have more than once said the British soldier in South Africa has had to fight physical geography as well as a stubborn, well-armed, and often invisible foe employing a new system of tactics. The military operations have been continuous and incessant, and the marches have probably been unprecedented in number, length, and difficulty—indeed, there is hardly any phase of warfare which our troops have not experienced. Lord Roberts, it must be remembered, has been a warrior from his youth up and consequently knows what war is. It is, therefore, quite refreshing to read the estimate which he has formed of the work which he has seen going on under his eyes as compared with the fault-finding, captious criticisms or light-hearted levity with which such matters have been too often regarded by amateur dabblers in war. We may depend upon it that foreign nations and foreign armies, whatever may have been said to the contrary, in their hearts are very much of the same opinion about the qualities of British troops as that expressed by Lord Roberts in his farewell order to the army in South Africa.

THE COLONIAL TROOPS ENTERTAINMENT.

On behalf of the committee appointed to make arrangements for the public reception and entertainment of the representative colonial contingent of forces serving in the War in South Africa, which is expected to arrive in England early next year (as well as the Canadian contingent now here), the Duke of Abercorn appeals for liberal assistance in a letter to the press. A very heavy expense must be incurred to give these troops a welcome in some degree worthy of the national appreciation of their splendid services. The officers and men of these contingents, numbering over 5000, will be brought to, and maintained in, this country and will be afterwards conveyed to their homes at considerable expense, the necessary funds being provided by Parliament, but such funds will not be chargeable with the cost of functions and entertainments not of a strictly military character, nor with the conveyance of the men to provincial cities or other places of interest. Over 5000 men have to be entertained and while it is hoped that large subscriptions will be tendered by those who can well afford it smaller contributions of any amount will be gladly received. Remittances may be made to the credit of the "Colonial Troops Entertainment Fund" at Messrs. Parr's Bank, Limited, 77, Lombard-street, E.C., or to the secretary or the treasurer, at 71 and 72, King William-street, E.C.

ARMY MEDICAL SCHOOL, NETLEY.

Under orders from the War Office a special examination was held in the Army Military School on Nov. 25th and 26th for the surgeons-on-probation of the Royal Army Medical Corps who were admitted to the school on Oct. 1st by examination and nomination by the Secretary of State for War on the recommendation of the medical schools of the United Kingdom. As a result of the examination the following gentlemen were recommended for commissions as Lieutenants in the Royal Army Medical Corps:—

SURGEONS-ON-PROBATION BY EXAMINATION.

H. J. McGrigor.
W. R. S. Goodwin.
J. H. Brunskill.
A. C. Duffey.
A. W. Gibson.
C. D. Myles.
R. N. Hunt.
H. E. Howley.
R. F. M. Fawcett.

SURGEONS-ON-PROBATION BY NOMINATION.

W. L Steele.
H. A. Davidson.
T. Finucane.
J. W. West.
W. Riach.
H. R. Bateman.
H, G. Pinches.
T. T. White.
J. C. Kennedy.
A. R. C. Parsons.
J. B. Cautley.
W. M. B. Sparkes.
S. B. Smith,
E. W. Powell.
J. L. Jones.

MEDICAL OFFICERS IN ACTION.

Medical officers, whether belonging to the regulars, colonials, or volunteers, have not spared themselves in the present war. They have not been behindhand in gallantry or in risking their lives and limbs on the battle-field. In the report of the late operations of General Paget's force north-east of Bronkhurst Spruit, where there was severe fighting, we read that Lieutenant Oswald Challis, R.A.M.C., was severely wounded, being hit in three places while gallantly attending wounded men under a heavy fire. We sincerely trust that this brave young officer may make favourable progress and soon recover. Surgeon-Captain Godfray of the New Zealand Mounted Rifles was also wounded in the same action. We are proud to say that there has always been the same spirit among medical officers throughout this war.

DEATH FROM INHALATION OF CHLORINE.—An inquest was held at Trowbridge, Wiltshire, on Nov. 30th, relative to the death of Miss Le Lean, aged 30 years, a lecturer under the Wilts County Council. Evidence showed that the deceased on Nov. 27th was attending a class of practical chemistry at the Bradford-on-Avon Technical Schools. During the temporary absence of the other students she took up one of the jars containing chlorine gas and, thinking it was empty, inhaled the fumes. She was taken violently ill and, in spite of medical attendance, she died two days afterwards. The jury returned a verdict that death was due to syncope arising from chlorine gas inhaled by misadventure.

Correspondence.

"Audi alteram partem."

POISON IN BEER.

To the Editors of THE LANCET.

Sirs,—Will you permit me to reply through your columns to the numerous requests which have reached me from all quarters for some indication of the views of myself and friends interested in the Pure Beer Movement upon the lamentable epidemic of poisoning in Manchester and other towns. Without anticipating the result of the scientific investigations now in progress there would appear to be little doubt that the epidemic is a striking illustration of the public danger to which we have for many years directed attention, arising out of the liberty permitted to brewers to use any materials they choose in the brewing of beer. This liberty is enjoyed under what is popularly known as the "free mash tun"—a concession granted by Mr. Gladstone when he repealed the malt tax in 1880. So largely did the brewers avail themselves of this freedom in the choice of ingredients that within a few years a movement was inaugurated with the object of securing a definition of "beer," and for many years subsequent to 1885 a Bill was annually introduced in Parliament for the purpose of obtaining such definition. In 1896 the Bill, which, with the assistance of members on both sides of the House, had been amended and amplified, reached the second reading stage; but on the Chancellor of the Exchequer offering a Departmental Committee to inquire into the matter the Bill was withdrawn. The sittings of this committee extended over two years, the outcome being a majority report against any alteration of the existing law, and a minority report strongly insisting upon the necessity of safeguarding the interests of the public.

We are of opinion that recent events are a complete justification of the minority report, and that had the Government acted upon its recommendations the present epidemic might never have occurred. It was pointed out that the fact of brewers being free to make beer of any materials they pleased so long as the revenue did not suffer rendered necessary much more scrupulous regulations for the protection of the public against the use of deleterious ingredients than at present exist.

Although there is no article of food consumed on anything like the scale of beer in the manufacture of which the indiscriminate use of any chemical or other material is permitted by law, the system of examination followed by the Excise officers in the breweries and by the Inland Revenue officials at Somerset House is designed for the protection of the revenue and not the detection of deleterious ingredients, so that the presence of any dangerous impurity is never likely, under existing circumstances, to be discovered until after the mischief has been done.

Notwithstanding that the Treasury may be "empowered" to prohibit the use of anything noxious or detrimental, the evidence taken by the committee went to show that this power has never been exercised save in the case of saccharin, a preparation believed to be harmless, but which was regarded as "detrimental" to the revenue. Further, the fact remains that the present epidemic has occurred in spite of official precautions, whatever they may be. And so long as the present system is allowed to continue so long will the door remain open to the use of poisonous or deleterious ingredients. It was also demonstrated to the committee by public analysts of high standing that they were powerless in the matter, as the Provisions of the Food and Drugs Act were inoperative as regards beer. Surely the time has now come when a period should be put to this subordination of public health to the interests of the revenue.

Sir Henry Primrose, the chairman of the Board of Inland Revenue, was congratulating the Country Brewers' Society the other day on the excellent relations which subsisted between his department and the great brewing interest, and he thought the attacks on the "free mash tun" might be regarded as at an end. As he is further reported to have said that he entered upon the "Beer Materials" Inquiry with the "blank impartiality which is born of blank ignorance," one is tempted to imagine, having regard to the strange way in which the conclusions of himself and the majority of the committee have been falsified by recent events, that he must have emerged from the investigation in much the same state of "ignorance," minus the "impartiality." I only refer to these utterances of Sir Henry Primrose because they are typical of the attitude which has been habitually adopted by the department over which he presides on this important question.

Every brewer knows perfectly well that the employment of invert sugar, glucose, &c., in the preparation of which dangerous chemicals are used is not necessary to the successful manufacture of beer. They enable beer to be matured more quickly and therefore larger quantities can be turned out with the same capital, plant, and storage room, and there is this further advantage, that by keeping down the demand for barley its price is correspondingly depressed and brewers are able to purchase such quantities as they are *obliged* to use at a cheaper rate. It is in the light of these facts that Mr. Read in his report asks that the complaints about British barley and the statement as to the *necessity* of getting "sun into the mash tun" should be regarded. Abroad the use of substitutes has in some States been for centuries absolutely forbidden; in Bavaria, it is a criminal offence, and not only the public, but the brewers themselves, are most active in seeing that the law is strictly enforced. It is difficult to see why that which is found not only desirable, but practicable, there should be regarded as impossible here. At any rate, the wholesale poisoning which has unfortunately occurred only goes to prove the necessity for still greater exertions in prosecuting the movement for better securing the purity of beer, and certainly justifies the opinion of Mr. Read, based upon a careful consideration of all the evidence placed before the Beer Materials Committee, that legislation or other provision is necessary to prevent the use of deleterious substances in brewing.

We propose to bring the matter again before Parliament at the first opportunity, feeling as we do that the time has surely come when the same protection as is afforded to the purchaser of other articles of diet, such as butter, milk, coffee, &c, should be extended to the immense number of our fellow-countrymen whose regular and favourite beverage is beer.

I am, Sirs, yours faithfully,

CUTHBERT QUILTER.

House of Commons, Dec 4th, 1900

To the Editors of THE LANCET.

Sirs,—It will be found that cases of arsenical poisoning are not confined to the Manchester district but are very widespread. The medical profession in Ilkley-in-Wharfedale have been greatly exercised during the last four months at the unusual number of severe cases of peripheral neuritis and acute skin affections that have come under their notice, for the most part occurring in beer-drinkers. The beer has been suspected for some months past as being the cause. But as no chemicals or preservatives were used in the local brewery that largely supplies the district the situation was perplexing. At one time I thought formalin might be the cause as in some breweries it is used to cleanse vats, bottles, casks, and also as a preservative in cheap beers. The brewery authorities were keenly active in endeavouring to fathom the mystery and ordered an analysis a month since, but unfortunately the analyst only looked for what ought to be in beer. Arsenic has now been found in the "invert" sugar used in the brewing and also in the beer. There are also an unusual number of cases of peripheral neuritis under treatment, of influenzal and rheumatic origin, occurring in non-beer-drinkers. Some of these are possibly of mixed origin. Aerated waters are not above suspicion where sulphuric acid is used to produce the gas.

I am, Sirs, yours faithfully,

A. H. BAMPTON.

Ilkley in Wharfedale, Nov. 30th, 1900.

"TREATMENT OF BRITISH PRISONERS OF WAR AT PRETORIA."

To the Editors of THE LANCET.

Sirs,—As a reply to your remarks in your issue of Sept. 22nd, 1900, it seems to me that I cannot do better than enclose a copy of a *letter* I have sent to the Field Marshal Lord Roberts—an answer to which I have not yet received. I saw the report for the first time quite accidentally and my astonishment can be imagined when it is known I had no idea there was anything of the sort. I do not think the method of a court of inquiry is understood. There was no clerk to make a record of the proceedings, the evidence was not on oath, there was no confrontation of witnesses or cross-examination. I was ignorant that there was any allegation against me, did not know of the witnesses or who they were, had no opportunity of cross-examining or in any way meeting the evidence which was not disclosed to me. I have had, therefore, no opportunity of defending myself. It is remarkable that the very obvious desire of some of the witnesses to exculpate themselves or gain *kudos* at my expense did not create some suspicion in the mind of the court.

I am, Sirs, yours faithfully,
H. PRIOR VEALE.

Hout Bay, Cape Division, Cape Colony, Nov. 12th, 1900.

Hout Bay, Cape Division, November, 1900.

To the Field Marshal Lord Roberts of Kandahar and Waterford,
K.P., G.C.B., G.C.S.I., G.C.I.E., V.C., Commander-in-Chief
of the British Forces in South Africa.

MY LORD,—I am persuaded that your lordship would regret any act of injustice which upon mistaken information you might possibly commit, and I approach you with a confident hope that you will cause further and more complete inquiry to be made and will not hesitate if and when satisfied that you have drawn in error a conclusion most injurious to myself to remove from my good name the shadow of your heavy adverse reflection. In a letter from your lordship to the Secretary of State for War, covering the report of the proceedings of a Court of Enquiry held with regard to the treatment of British prisoners of war in Pretoria, the following passage occurs:—"On the other hand it would be difficult to condemn too strongly the conduct of Dr. H. P. Veale, M.B. (Cambridge), whose heartlessness in ignoring the disgraceful treatment of the sick prisoners and the remonstrances addressed to him by the medical officers in immediate charge of them calls for the severest reprobation."

From the passage above quoted, read with the letter from Colonel Hunt, I must infer that your lordship supposes me to have occupied some official or recognised position in which I could have remedied the condition of affairs regarding prisoners of war. The statement to this effect made by Colonel Hunt in his report naturally and probably weighed greatly with you. I beg, therefore, plainly to point out to your lordship that though a member I never was head of the Red Cross Society nor at any time occupied any official position giving me any authority or control with regard to the prisoners of war. Such services as I rendered in connexion with the prisoners of war at the Racecourse and elsewhere were rendered gratuitously on humane consideration only. I may mention incidentally that the Transvaal Red Cross Society depending on public voluntary subscription none of its members or servants to my knowledge received any remuneration. The administration of matters affecting prisoners of war was placed by the State as a distinct department under a specially appointed committee to which the charge of the sick and wounded was allotted. This appears from the separate resolution of the Executive Council appointing the "Medical Commission" and conferring on it jurisdiction over all medical matters and men in the State *except the prisoners of war*. I was associated with the Medical Commission, but was at no time engaged in the distinct department mentioned or by the Prisoners' Committee, and it may be questioned whether, according to the Executive Council resolution, I could have been so engaged. Be that as it may, I had no function or appointment in that connexion. But it may be felt that though I had no official position to redress evils of administration, yet as a graduate of a great British University something more might be expected of me than of other medical practitioners. On this head I beg to point out that I used such opportunities as I had not merely for ameliorating the condition of things of Waterval, but with a view to preventing that spot being used as it was. I would point out that I dreaded what might happen there and most cheerfully seized the opportunity given me of inspecting Waterval on the 27th December, 1899.

On the 28th December, 1899, I sent a report totally condemning Waterval as a site for a camp. I had the water analysed and I forwarded to the Prisoners' Committee the report condemning it as unfit for use. In order that they should not be overlooked or forgotten I repeated these reports on the 12th January, 1900, to emphasise the danger the Prisoners' Committee was running. Copies of these letters were given by me to the Court of Enquiry. To prevent mischief to health at Waterval I on the same date further pressed by letter upon the Prisoners' Committee that the sick should be immediately removed to the Racecourse, feeling certain that this step would reduce the risks entailed by the distance of Waterval from Pretoria (copies given to the Court of Enquiry). In addition to these written efforts, and quite beyond any official function entrusted to me, I urged verbally on officials highly placed under the Government and on members of the Prisoners' Committee the above or other means for preventing or ameliorating the unsatisfactory state of affairs. I was more than once told that the Prisoners' Committee did bring the matter before the Executive Council who, however, refused to alter matters. On the 16th January, 1900, I urged (copy handed to Court of Enquiry) the Prisoners' Committee to appoint Dr. Haylett as resident "responsible" medical officer of the committee at Waterval, in the hope that if the committee went so far it would also enable the officer to do his work under proper conditions. His first appointment to Waterval, dated 27th December, 1899, did not speak of responsibility and my suggestion was to make Dr. Haylett, the officer at Waterval, responsible for the sick and wounded to the committee who should support him. Dr. Haylett, in full knowledge of the condition of affairs, accepted the 16th January, 1900, appointment, but I cannot say to what extent also he used his position to influence the members of the Prisoners' Committee and to press on steps desirable. He may have done so ineffectually. What I wish to emphasise is that he was in a position independent of myself. When holding the temporary position of commissariat officer to the "Medical Commission" I again tried to help the prisoners and wrote to the Prisoners' Committee (24th Feb., 1900, copy given to Court of Enquiry) urging it to arrange for placing the sick and wounded prisoners under the "Medical Commission," so that burghers and prisoners could be treated alike, and the reply I got was that the Prisoners' Committee was satisfied with things as they were. I also urged through the State Attorney, who was a member of the "Medical Commission," that those prisoners who came under the release clause of the Geneva Convention should be released. I worked this until Dr. Bierens de Haan and myself were appointed a board to report on the physical condition of certain prisoners. We reported that three officers and some men came under the clause. Their release was ordered and the time of their departure fixed, but at the last moment an order came from the Government, countermanding the order of release because the Commissioner of Police did not think the Convention applied. I urged the State Attorney to advise the State Secretary on the matter, which I believe he did. The men, however, were not released, though the officers were subsequently in some ill-defined way.

That I did urge, and was anxious to give, assistance to the prisoners, the best assistance in my power, is clearly shown from what took place with regard to the officers. When an officer became ill in his quarters I was only able to give medicines, suitable diet, alteration of his sleeping quarters, and other things equally necessary I was not allowed to interfere with; but when I could get the necessary permission and remove the sick to the Bourke Hospital (of which I was in charge for the Red Cross Society) there was nothing procurable and suitable that such sick did not receive. This shows that when I was able to act free from the Prisoners' Committee I was successful in securing proper treatment of the sick. I would here remark incidentally that the Government or its subordinates gave no help whatever to the sick and wounded officers in Pretoria and that everything they received was obtained by me in the first instance from the Red Cross Society and later from private sources.

I venture to hope that if your lordship will kindly give attention to the above true representations as to my position and what I did, you will conclude that not having been appointed by the Government to look after the prisoners not only was I not officially responsible for what was left undone, but further as an ordinary medical practitioner I did not ignore any lack of proper treatment brought to my notice, but did what I could to improve the circumstances and alleviate the sufferings of men as well as officers. Upon representations which have been erroneously made your lordship, it appears, has judged me adversely as having ignored remonstrances addressed to me by other medical officers. This can only apply to one medical officer—viz., Dr. Haylett. This gentleman's appointment was specially urged by me because I thought that with his knowledge of the Dutch language and acquaintance with the officials he might perhaps achieve much improvement at Waterval, when, prior to his appointment of the 16th January, 1900, which made him responsible, he wrote to me on the condition of affairs at Waterval on the 27th December, 1899, this matter was being dealt with by the appointment of the inspecting commission previously mentioned in this letter. I had his letter translated into the official language and forwarded it the same day with a covering letter to the Prisoners' Committee (copies handed to Court of Enquiry). Then Dr. Haylett wrote again re-stating the condition of affairs and also stating that he had interviewed the Prisoners' Committee. I told him that I was not the proper person to write to and advised him to continue to address the Prisoners' Committee and the Executive Council, but said that if he would write his letters in Dutch (the official language) I would forward and support them. He had, in fact, caused me unnecessary trouble in getting his previous letter forwarded as I had to get someone to translate it—not being able to do so myself and I had no secretary, as has been stated. The other notes I received from him being requests for medicines were at once handed to local chemists for execution and he received these consignments without delay. I had, indeed, also informed him that it was, strictly speaking, the duty of the Prisoners' Committee to supply him with medicines, but I was willing to see to these supplies and did so, as he held, not without reason, that it was vain to expect the requisite prompt attention from the Prisoners' Committee. It is not easy to understand how Dr. Haylett could seemingly have believed that I was the chief medical officer, and it is noteworthy that when he approached the Prisoners' Committee on the 7th January, 1900, he does not appear to have made complaint as to his unanswered letters. In this connexion I may refer incidentally to his letter dated the 7th January, 1900, which was handed to the Court of Enquiry. His action throughout scarcely supports his assumed attitude as my subordinate. Dr. Haylett did not, as must be inferred from the statement recorded, tender his resignation by way of protest against his unsatisfactory position, but it will be found that he resigned rather because the Pietersburg Railway Company would otherwise be unable to continue his appointment as their medical officer. In fairness to myself I must call your lordship's sttention to the fact that it was not possible for me at the Court of Enquiry to meet allegations against me which were not disclosed or known to me, and when at a later date the apprehension that I was regarded unfavourably caused me to write to your lordship the interview which I had with Colonel Cowan removed it. At this distance in Cape Town I am somewhat handicapped in presenting my exoneration, as, of course, I have not with me all the materials which would be available at Pretoria.

There is a special point of fact in Colonel Hunt's report which may, perhaps, have contributed to place blame which cannot justly attach to me. I refer to his remarks with regard to the sick in the gaol and their non-removal. No other medical man being mentioned by name it may be supposed that I am referred to, whereas the gaol was and is under the district surgeon. Colonel Hunt in the same letter attributes to me unworthy motives for action or inaction for which he believes me responsible or culpable and yet cannot have formed his conclusions from any personal observations nor can he have been aware of the fact that my position and practice were entirely independent of remuneration or reward from the Government of the State. It may be that your lordship will, amidst much more important work, find time and occasion to investigate my appeal and ascertain the facts which I have here loosely strung together, and I most earnestly trust that such reconsideration of my case may remove the stigma under which your censure leaves me before the world.

"THE QUESTION OF THE COMMUNION CUP."

To the Editors of THE LANCET.

SIRS,—Theologians and students of ritual will, I think, welcome the discussion in THE LANCET of the question of possible infection conveyed by the touch of the communion cup. Obviously there are two separate questions—one of medical fact, the other of ritual observance. The question whether infection may possibly or probably be conveyed by any given mode of administering holy communion is one for medical experts only; it is foolish for anyone else to give an opinion. It has, indeed, been suggested that communicants, obeying a Divine command, may commit themselves to the Divine protection against possible harm. I cannot put that suggestion summarily aside, because I believe in what is commonly called "miracle" as possible and not unfrequent; but I should meet it by a reminder of the theological commonplace that miracle must not be unnecessarily presumed either as an explanation of fact or as a guide to action; such presumption, therefore, is no excuse for doing a dangerous thing which is avoidable. It is technically presumptuous to hope for miraculous protection without taking all natural precautions. It is for medical experts alone to say whether any given precaution be adequate.

Is the peril, then, avoidable? If our actual practice be dangerous it is for ritual authorities to consider what may be substituted. There seems to be a tendency in some quarters to assume that no change can be made. I cannot understand this. Theologically speaking, it is to me inconceivable that God, Who reveals to scientific research the hidden perils of nature, has tied the administration of His Sacrament to a mode which that revelation shows to be harmful. Practically speaking, there are several modes of administration known in the Church. Careful consideration of the question will certainly be demanded. The *Church Times* was lately urging the English bishops to appoint a commission of inquiry. Even at the present stage of discussion it may be useful to recall the methods used.

In the greater part of the Eastern Church the method of *intinction* prevails, to which you have already referred. A kind of sop is made in the chalice, which is administered by a spoon. I believe the spoon is rinsed after each using, with what effect the proper experts may say. This method is not perhaps very likely to find favour with us.

In the West, before the withdrawal of the cup from the laity in the twelfth and following centuries, the sacred species was often administered by suction through a *fistula* or metal tube. This would probably be even more open to objection than our practice, in which the lower lip only comes into bare contact with the outside of the cup.

Early in the eighth century the Pope, St. Gregory II., forbad the use of many chalices on the altar for symbolical reasons, requiring all to communicate from one cup. This brought in the use of very large vessels, from which the sacred species was poured into smaller cups, called *scyphi*, for the communion of the people. This may show that no theological or ritual exception can be taken to the use of a separate cup for each person, advocated by your American correspondent, but there is an overwhelming practical objection where any large number is concerned. The rule of the English Church requires the total consumption of the consecrated species by the priest, alone or with the help of some communicants. This cannot be effected save by the usual practice of pouring into the cup some wine or water, or both, and drinking this. The treatment of several hundred cups passes imagination.

There is a practice, not formally adopted, so far as I know, anywhere in the Church, but sometimes followed by individual priests in difficult cases of clinical communion, which may be worth mentioning. A particle of the species of bread is slightly tinged in the chalice and then laid on the tongue of the communicant. This method of giving communion presents little practical difficulty and might conceivably be adopted by authority for general use.

Some of your readers may be glad to have this material to work upon in their character of medical experts.

I am, Sirs, yours faithfully,

Madingley Vicarage, Cambridge, Nov. 28th. T. A. LACEY.

BERI-BERI AND CHRONIC ARSENICAL POISONING.

To the Editors of THE LANCET.

SIRS,—I trust that you will allow me to call attention in your columns to a point of some interest in connexion with tropical medicine raised by the present epidemic of peripheral neuritis in Chester and Manchester. The extraordinary similarity of some of the cases to certain phases of beri-beri seems to me to suggest the question whether many instances attributed to the latter disease may not really be due to chronic arsenical poisoning. Owing to the kindness of several medical gentlemen I had the opportunity of examining pretty carefully 10 of the Chester cases, and also of seeing several of those which had occurred at Manchester. I certainly thought that Dr. W. A. Newall and Dr. J. R. Prytherch of Chester were abundantly justified in noting an extreme resemblance between their cases and cases of beri-beri. The local anæsthesias, especially of the feet, of the tibial skin, and of the finger-tips, the dropsy over the tibiæ, the tenderness of the calf muscles, the loss of the deep reflexes, the ataxia combined with paresis, even the peculiar spacing of the heart-sounds in some instances, were all so suggestive that had the cases occurred in a beri-beri region I believe few medical men would not have returned them under that heading.

Assuming the cases to be due to chronic arsenical poisoning, we may well ask whether similar epidemics occurring in the East or on board ships may not often have been wrongly attributed to beri beri. The possibilities of arsenical poisoning on vessels are too obvious to need reference in detail. Natives of India and Burma are very fond of lemonade which is manufactured from European chemicals—probably of the cheapest sort. They also often delight in tinned and bottled fruits The occupants of jails, hospitals, and asylums may suffer from arsenical poisoning through half a dozen routes. The sudden disappearance of beri beri from the Japanese navy after a general change of diet is certainly suggestive. It has long been thought on epidemiological grounds that beri-beri may be due to some form of food-poisoning; it now seems just possible that the poison may be, at least in some cases, nothing but arsenic. The sudden improvement occurring in most cases after removal from the house where they contracted the malady is certainly more suggestive of intoxication than of infection. In short, regarding such epidemics of beri-beri as I have had the opportunity of witnessing, I should be sorry to be called upon to give a definite statement to the effect that they were not due to chronic arsenical poisoning.

Of course there may be, and very probably so, a true beri-beri, but the points of distinction do not seem to be very clearly established at present. I think I remember bullæ and even pigmentation in India. Certainly cases approximating to the "wet" form of beri-beri do not seem to have been noted in Chester; but this is, I think, a later stage of the disease, and may perhaps have been overlooked in chronic arsenical poisoning. Lastly, our knowledge of the epidemiology of beri-beri cannot be said to be so complete as to enable us to exclude all possibility of arsenic being concerned in the causation at least of many cases attributed to the disease.

In conclusion, I hope that it will be understood that I am only suggesting a possibility and that I do not presume to erect a theory. The next ship which arrives infected with beri-beri at an English port will afford an opportunity for an examination of the question.

I am, Sirs, yours faithfully,

Liverpool, Nov. 30th, 1900. RONALD ROSS, D.P.H.

"THE TREATMENT OF SPRAINS AND OF SOME FRACTURES."

To the Editors of THE LANCET.

SIRS,—For the last 20 years I have been treating sprains by the application of adhesive plaster and, like Mr. Christopher Heath, I have found this plan far more satisfactory than the older methods Since I first became aware of its value I have never omitted to use this plaster in some stage or other of the treatment of these injuries, even in sprains accompanying fractures I was first led to realise the advantages likely to result from so firm and steady a support as that effected by adhesive plaster when studying œdematous tissues microscopically for the purpose of the "Atlas of Histology." The plasma which in œdema is infiltrated into the connective tissue, separating almost every individual bundle from the others, seemed likely not only to prevent repair by its pressure, but also (from lack of complete absorption) to produce permanent thickening of the tissues by becoming organised.[1] This condition pointed to the desirability of preventing, if possible, this infiltration from taking place, and if it had already taken place of promoting its absorption, and the firm support without undue pressure given by adhesive plaster seemed just what was required.

---

[1] Atlas of Histology, Plate VIII, Fig 14.

In using adhesive plaster for this purpose certain precautions are necessary. No attempt must be made to produce pressure; the plaster must be laid on very evenly, being held only just sufficiently firmly to allow it to adhere without creases. It is necessary to use a plaster which does not require heating, and there are several so-called rubber plasters now made which are suitable. Strips from one to two inches wide are best, and they should just overlap each other. After a few days, or sooner, the plaster should be removed and fresh strips applied. If the deep tissues are not very severely injured it is well to precede the application by about five minutes or more of gentle massage (towards the heart). Massage is also very useful in the subsequent treatment whenever the plaster is removed. In addition to massage passive movement is generally beneficial. I have applied strapping in a case in which I feared gangrene of the tissues round an ankle, the joint not only having been sprained but the soft parts also severely crushed. The patient made a good recovery. I have also applied strapping in the case of a Pott's fracture which necessarily involved a severe sprain. The effect was to prevent swelling and thus greatly to hasten the cure; and as there was consequently very little infiltration of plasma subsequent stiffness of the ankle was prevented. If a sprained joint is already swollen when seen by the surgeon it is well to raise the affected part above the level of the body for a few minutes to allow gravitation of the blood and during this process the massage may be carried out and will help in reducing the œdema.

Although it is best to use the plaster from the first, yet the beneficial effect of this treatment of sprains is very noticeable when applied to patients who have undergone some days of treatment by the old plan—i.e., rest of the affected limb and the application of evaporating lotions. The swollen joint will be rapidly reduced in size by absorption of the infiltrating fluid after application of the plaster. In these circumstances we should remove and re-apply the plaster as soon as the œdema has visibly lessened, and this may be necessary every day, until very soon the joint will have assumed its natural size, in perhaps as many days as it would otherwise have taken weeks. The advantages of the adhesive plaster treatment are immense. Often the patient may begin to walk about directly the plaster is applied, and there can be no doubt that early use of the part as well as passive movement and massage assist the cure.

Dislocations.—The difference between a sprain and a dislocation is chiefly a matter of degree as regards the injury to parts surrounding a joint, and therefore the same considerations in respect to treatment should prevail. Without entering into details with which many of your readers must already be familiar I would sum up the treatment of dislocations as follows: 1. Reduction under an anæsthetic, in order to avoid unnecessary and detrimental disturbance of the injured tissues. 2. Support by means of adhesive plaster and light bandaging. 3. Early *passive* movement, commencing 24 hours after reduction and repeated daily. 4. Massage. 5. Early *active* movement.

Undoubtedly, there may exist complications which will necessitate a modification of this line of treatment, but in the majority of cases the above rules may be followed with advantage; the period of treatment will then be considerably shortened from that pertaining to the older methods, and stiff joints will almost certainly be avoided or much reduced in degree.

I am, Sirs, yours faithfully,

Queen Anne-street, W., Nov. 24th, 1900. NOBLE SMITH.

OLIVE OIL IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In view of the enormous mortality from enteric fever amongst the British troops in South Africa may I again bring before your readers a method of treatment advocated by myself in your paper about two years ago?[1] It consists in slowly administering every 12 or 24 hours an injection of olive oil per rectum. The quantity used for adults should be about a pint at a time, and should be retained in the bowel from 12 to 24 hours if possible. If not returned in this time it may be brought away with an ordinary soap-and-water injection, a fresh dose of olive oil being administered two or three hours later. After a week or 10 days the daily use of the injections can be discontinued, and they are given only when the temperature rises or the bowels are confined. With diarrhœa it is imperative to give olive oil, and those who try it will find it more efficient than opium or any other drug in bringing about a natural discharge of fæces. Occasional small doses of calomel from one-tenth of a grain to half a grain are useful if the oil is not sufficiently stimulating to make the bowels act. I use it now instead of giving olive oil by the mouth, which was found to be too nauseating for better-class patients. My only medicine for typhoid fever, in addition to olive oil and the above-mentioned occasional doses of calomel, consists of carbonate of ammonia, glycerine, and decoction of cinchona given every three or four hours. Whether this preparation has any beneficial effect or not I am unable to say; it has the virtue of being probably harmless, and without the glycerine was a favoured preparation of Percival Pott. With oil injections the bismuth preparations are quite unnecessary. Patients treated in the above manner in my opinion cannot die; for careful observation has led me to believe that typhoid *per se* is a harmless fever, it is the accompanying sapræmia or ptomaine poisoning which produces the ill-effects. Under this line of treatment there are no sequelæ, tympanites, perforations, or heart failure. No cold baths are necessary. The most unskilled nursing is sufficient. Its only drawback occurs in private practice, where patients get well so easily that no credit accrues to the physician. Medical friends in Australia and Canada endorse my opinion as to its value.

I have heard that olive oil given per rectum has been found post mortem in the stomach less than 24 hours after administration; if this is true it is of extreme interest as showing that the beneficial effects of the oil extend above the ileo-cæcal valve. During a visit home last year a bacteriologist hinted that my patients were not suffering from true typhoid fever, but from some fever due to a closely allied bacillus. I can only state that my friend Dr. W. T. Dermer examined a large series of cases here and obtained Widal's reaction in nearly all of them. Large bodies of men, as armies or gold-prospectors, who invade an undeveloped country, are invariably attacked with typhoid fever—witness West Australia, Klondyke, the Cuban campaign, and South Africa. My own hypothesis is that the bacillus present in virgin soil acquires virulence by passage through a series of hosts. An old prospector informed me that he knew of numbers of typhoid-stricken places in Australia which had completely cleared themselves in a few years without any attempt at sanitation. Do the inhabitants and their children acquire immunity or does the bacillus lose its virulence? People alone in the bush, living on apparently virgin soil, can develop typhoid fever. In the case of my own child, aged two and a half years, who nearly died from enteritis (not typhoidal) accompanied by a recrudescence of malaria, and who on recovering from the acute stage daily passed casts of the intestine, the condition was completely cured in from two to three weeks by injections of olive oil, protargol and other remedies having been used in vain.

I am, Sirs, yours faithfully,

OWEN F. PAGET, M.B., B.C. Cantab.

Fremantle, Western Australia, July 21st, 1900.

"PROFESSOR LUSTIG'S PLAGUE SERUM."

To the Editors of THE LANCET.

SIRS,—I am much indebted to your special Indian correspondent for excusing my "personal attacks"—so he is pleased to call the repudiation of his erroneous assertions—on the plea that "such attacks may be common in debate on the continent of Europe," and in return I cordially sympathise with him on "an extraordinary thing" which happened to him in his reply in THE LANCET of Sept. 22nd, page 903—viz., to pose as a martyr correspondent "who cannot criticise without ignorance or wilful misleading being put forward to explain his opposition," and at the same time to substantiate in a most creditable manner the first of the two alternatives he is complaining of. The present controversy arose from your special correspondent's insinuation in THE LANCET of June 2nd, page 1608, that in the second series of the experiments with Professor Lustig's plague serum *selection or exclusion* of patients was practised. Although from my letter in THE LANCET of

---

[1] THE LANCET, August 13th, 1898, p. 409.

August 11th, page 461, that fact might have been known to him, who emphasises his English extraction, he still professes in his reply that we are at issue upon the "construction and reading of the statistics," and innocently repeats twice more "that moribund and convalescent cases were excluded." These assertions—I beg his pardon for betraying again my continental training—are *not correct.* Neither in my paper and letter on the subject, nor in Lieutenant-Colonel Wilkins's letter in THE LANCET of August 11th, page 462, is any mention made of *moribund and convalescent* cases. There is only the plain, intelligible, and correct statement, that in the *second series* of the experiments the cases were not selected but treated *alternately as they were admitted* to the hospital. Tested in this way, which was agreed upon with the municipal commissioner of Bombay in order to obtain results above suspicion and discussion, the serum treatment has given 12 per cent. more recoveries than the ordinary treatment. I can therefore show, as your special correspondent challenges me to do, "a series of cases in which every admission has been included and in which the serum cases show better results than the others." This might satisfy your conscientious special correspondent as to the *conditions of the experiments and permit him "to be glad* to accept my conclusions," and it ought to end a controversy where the advantage is entirely with me, who can put facts controlled by the responsible authorities on the spot against assertions of a distant and, it seems, an irresponsible special correspondent.

I may be allowed to add that 484 patients had alternately been treated on either side when the experiments were concluded in July last by order of the municipal commissioner, who having satisfied himself that the results are real decided to have the serum manufactured on a still larger scale for the coming epidemic. The staff and stock of the municipal laboratory were *therefore increased accordingly*, so that at present 25 horses are under immunisation. Finally, I beg to correct a misprint in my letter in THE LANCET of August 11th (page 462), where the recovery rate of the *selected cases* is put down as 33·2 per cent. instead of *38·2* per cent., an error your special correspondent might have found out from my paper which gives the correct figures.

I am, Sirs, yours faithfully,

A. MAYR, M.D.

Municipal Laboratory, Parel, Bombay, November, 1900.

THE ASSOCIATION OF PHYSICIANS AND SURGEONS (SOCIETY OF APOTHECARIES).

To the Editors of THE LANCET.

SIRS,—Referring to an announcement in THE LANCET of Nov. 17th, p. 1461, with regard to the abbreviated titles which may now be used, we wish to remind holders of the licence of the Apothecaries' Society of London that they are still required to sign *death* certificates with the letters L S.A. as formerly.

I am, Sirs, yours faithfully,

GERALD DALTON,

Honorary Secretary to the Association of Physicians and Surgeons (Society of Apothecaries).

Nov. 29th, 1900

THE OPEN-AIR TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—It will no doubt be thought somewhat in the nature of heresy at the present time to question the advantage to be derived from the outdoor treatment of phthisis, but I cannot help thinking that the new idea is likely to undergo considerable modifications, like most other previously proposed suggestions. When a student at St. Thomas's Hospital, now nearly 40 years ago, I noticed that but few of the patients left the wards without having had a cold of some kind—bronchitis or pneumonia—during their time of residence, and there, of course, the windows were kept open night and day. Years ago the climate recommended as likely to benefit phthisis was a sunny, warm, and damp one, such as prevails at Ventnor, Torquay, Cannes, Nice, &c., and no doubt in certain cases this may prove of service; then came a change of view, and cases were advised to go to dry, cold, elevated positions, such as the Engadine, Colorado Springs, &c. The result of this treatment in many cases *has been proved to be decidedly* beneficial; but now we have come back apparently to the idea that dryness of the air and elevated positions are of little consequence provided the patients have pure air and plenty of it, a view in my opinion decidedly retrograde. Hitherto we have been led to believe that warmth and moisture rather tend to promote germ life, and a particularly rare and cold air tends to increase the bodily vigour and natural powers of resistance. Under any circumstances I should say that in the present experiments two things should be considered—the direction of the wind and the amount of moisture in the atmosphere. The bedstead should always be so placed as to avoid the direct current of any air but from the south or west, and when the air is moist it should be dried by means of wire-framed antiseptic cotton-wool screens and not allowed to come direct into the patient's room. Everybody is well aware that many persons in sound health cannot stand a cold and damp atmosphere, especially at night A certain number of patients recover under each of the different methods of treatment, but what we want to know are the actual comparative results of the various suggested methods.

I am Sirs, yours faithfully,

Dec. 3rd, 1900 F. P. ATKINSON, M.D. Aberd.

ECONOMY IN THE EMPLOYMENT OF COCAINE.

To the Editors of THE LANCET.

SIRS,—The prevailing high price, with the occasional personal intolerance of cocaine and its *salts*, suggested experiments with the view of reducing the quantity employed and increasing its efficiency when used in ear, nose, and throat work. In the first place it was found that a 2 per cent. solution of the *alkaloid* in equal parts of almond and petroleum oil proved an efficient local anæsthetic for the *examination of, and slight operations upon, the nose and* throat—e.g., passing Eustachian catheter, laryngoscopy, exploration and removal of foreign bodies, &c. Applied either by means of an atomiser or a cotton-wool "swab," although apparently taking a little longer to act, its anæsthesia is more prolonged than that produced by a *watery solution: probably owing to the fact* that oil is less readily removed by the flow of secretion. With regard to the *salt*, a watery solution containing cocaine hydrochlorate 5 per cent. and sodium sulphate 2 per cent. was eventually selected. This addition of the neutral sodium salt decidedly increases the effectiveness of the cocaine, partly by reason of *its penetrating power* and *partly* owing to its solvent action upon the globulins and other proteids which occur in the secretions The former quality is well illustrated in the influence of Muller's fluid on tissues, the chromic salt penetrating readily under the influence of Glauber's salt. The action of the combined solution proved to be distinctly *more* rapid, and the anæsthesia was as complete with a proportion of 5 per cent as with cocaine in much stronger solutions by itself. Economy is effected and the risk of constitutional symptoms is minimised. When either submucous or subcutaneous injection is required, eucain hydrochlorate (5 per cent.) may be combined with 2 per cent. *sodium sulphate* with equal advantage, but when used as a surface application to mucous membranes, eucaine should be followed or combined with a solution of suprarenal extract, if local ischæmia be desired.

I am, Sirs, yours faithfully,

WYATT WINGRAVE, M.D.,

Physician Central London Throat and Ear Hospital.

Dec. 4th, 1900.

THE LEAGUE OF MERCY.

To the Editors of THE LANCET.

SIRS,—*The recent appeal of* the Prince of Wales's Hospital Fund to the public for subscriptions raises the question of the wants of the London hospitals. This Fund has been productive of enormous benefit to the hospitals, not only in the direction of financial assistance, but by causing improvements and reforms to be carried into effect. The Prince of *Wales's Hospital Fund* has mainly been supported by generous donors and subscribers of large amounts.

It is known that there are vast numbers of persons who, willing and in many cases anxious to contribute, are unable to give largely, and to meet these cases the Prince of Wales established the League of Mercy, now founded by a Royal Charter. The constitution of the League is so arranged that contributions of 1*s.* or upwards may be made through members of the League, who, working under presidents and vice-presidents in all parts of London and the home counties, are in a position to obtain help for the hospitals which would not otherwise be received.

If everyone who does not in any other way subscribe would contribute 1*s.* to the League of Mercy through a member the needs of the hospitals would be supplied. In this way the special appeals from hospitals which from time to time are made would not be required. It would be a distinct advantage if these special appeals could be avoided. They have many objectionable features, one being that they dislocate the sources of charity, as the war and famine funds have done during the past year. It may be stated that every farthing of every shilling given to the League goes direct, without any deduction for expenses, for the benefit of the London hospitals.

The League of Mercy was organised to secure some measure of personal service on the part of a large number of persons who are sufficiently conscious of the value of our London hospitals, and are willing to devote a little time and trouble to bring their needs and the services which they render to the public to the notice of those who have hitherto, from want of opportunity or knowledge, taken no interest in this work. The organisation of the League has now permeated throughout London and the home counties, and we would be very glad to have offers of personal service or to give information as to how good work can be done by anyone who is prepared to give a little time each year on behalf of the hospitals.—We are, Sirs, yours faithfully,

WOLVERTON,
W. J. COLLINS, } Honorary Secretaries.
J. HARRISON,
Nov. 30th, 1900. HENRY C. BURDETT, Treasurer.

"THE MICRO-ORGANISMS OF VACCINE MATERIALS."

To the Editors of THE LANCET.

SIRS,—I have just seen Mr. Arthur W. Hare's letter in THE LANCET of Nov. 24th (p. 1532) dissociating himself from the conclusions in my paper on "The Micro-organisms of Vaccine Materials." This is not surprising, as I willingly admit that Mr. Hare was a monomorphist of the most severe type from the bacteriological point of view. I must, however, demur to being denounced as a polymorphist of a dangerous type. Mr. Hare says that "a spore is not to be looked upon as a definite cause of disease." May I venture to point out that intestinal anthrax is produced by spores only? The rods appear to lose their active power of producing the disease in the stomach, but the spores pass through the stomach unaltered and germinate in the intestine. The paper appears to be self-explanatory as to my views upon the life-history of a pathogenic micro-organism. Then Mr. Hare pleads for respect to the dictum that "like produces like." Cohn, Brefeld, and Koch do not put it that way. Cohn started from the assumption that each species was characterised by a definite form, but he was not sure whether his form species coincided with natural species. Brefeld, Koch, and others have shown that some species are monomorphous, others show pleomorphism in various degrees, as when spores give rise to bacilli and the bacilli in turn produce spores. The decision arrived at was that there are distinct species of bacteria which may be distinguished by following their development. I claim to be a pleomorphist in that sense, as where this cannot be done form species may not coincide with natural species. My work was chiefly devoted to the definition of the composition of natural vaccine and variolous material and to ascertaining the cause of opacity in lymph, and I am quite prepared to leave it to the tender mercies of the specialists whose aid Mr. Hare has invoked. I am, Sirs, yours faithfully,

Edinburgh, Dec. 3rd, 1900. JOHN B. BUIST.

"THE USE OF TOBACCO ON ACTIVE SERVICE."

To the Editors of THE LANCET.

SIRS,—In his criticism in THE LANCET of Dec. 1st (p. 1612) of your annotation under the above heading Dr. R. Martin accuses its writer of basing his opinion "on the flimsy ground of mere hearsay," but is his own eye free from motes? Dr. Martin asserts "that where healthy men have undergone severe fatigue in the open air they will speedily sink into profound repose, when the fitting time arrives and opportunity serves, however scanty the diet may have been." Now, according to my experience—and I have been through several campaigns—many men on service are afflicted with insomnia, especially, though by no means exclusively, when new to the conditions. There is such a thing as being over-tired, and when excitement is added sleep of any kind, let alone "profound repose," is often wooed in vain. Then it is that the value of a pipe becomes priceless, as it induces refreshing sleep. I believe also that tobacco is a great aid to digestion in men who have to live and to work hard on unusual food, such as biltong or "bully beef," and so far from drying and irritating the fauces "the fumes" are well known among soldiers as a thirst-quencher in the absence of water. In order to pose consistently as one who has not "meddlesomely tampered with nature's kindly process" a man should, amongst other things, go naked, eschew cooking, and leave his chin unshaven. We live artificial lives, and to base an argument on the kindness of nature is a slap in the face to civilisation.

In conclusion, I should like to know Dr. Martin's authority, beyond hearsay, for his assertion that "the best shots at Bisley are almost invariably non-smokers." My recollection does not tally with this positive statement.

I am, Sirs, yours faithfully,

Dec. 3rd, 1900. PYRAMID.

REPORT OF PLAGUE IN CALCUTTA.

(FROM A CORRESPONDENT.)

A REPORT nominally by the Chairman of the Board of Calcutta has recently been issued. As the officer in whom all power is vested the report comes from him, but it is based on the work of the plague department. This department has been successively presided over by Mr. J. Nield Cook, Major Green, I.M.S., and Major Deane, R.A.M.C., all of whom contribute their several quota to the volume. The chairman's portion is a compilation from, and summary of, the other reports. The striking feature of this record consists in the abandonment of every plague measure except that of disinfection. At no time during the epidemic has anything else been enforced. Patients have not been compulsorily removed, contacts have not been segregated, evacuation has been untried, and inoculation has only been sought by a few. Until the present year Calcutta has not had a serious outbreak, so that the absence of strict measures can hardly be said to have facilitated the progress of the disease. The total estimated mortality from plague since its first official announcement in 1898 is only 13,000. The people have sickened and died in their own homes, and as there has not been any compulsory disturbance of the privacy of the home it is not surprising to find that less than 20 per cent. of the returned cases of plague were seen during life. The system of investigation seems as complete as it can possibly be. Every death reported to the registrar is submitted to the district medical officers who, with their assistants, institute inquiries from the relatives, friends, and neighbours into the course of the illness. By this systematic examination a certain number of deaths are returned by the district medical officer as due to plague, others are returned as suspicious, and the remainder as not suspicious. So thorough has this method been that the excess mortality of any period can be accounted for by the plague and suspicious deaths. Where so large a proportion of the population die without any medical attendance whatever it is impossible to adopt any more accurate method. All the work of the epidemic has fallen on the plague department, as very little assistance has been given by householders, medical practitioners, or influential natives. Less than 5 per cent. of the cases went voluntarily to the two general hospitals.

Inoculation can hardly be said to have had a fair trial in Calcutta. Little or no encouragement has been given to it and less than 500 operations have been done during the past two years. It may truly be said that disinfection of the houses has been the only policy pursued. This has been carried out for every suspicious death and latterly on a wholesale scale for nearly every street in the city.

An innovation of great importance consists in allowing and indeed persuading the people to return to their rooms immediately after disinfection. This practice is adopted on faith in the value of disinfection and with the object of reducing inconveniences for householders to a minimum. The other striking plan adopted in Calcutta has been the wholesale disinfection of streets and large collections of houses. This is known as "extra disinfections." The idea appears to be to *anticipate a further outbreak by destroying any poison* which may be lying latent. It is a great experiment, and the value of disinfection for an Indian city, in the case of plague at any rate, must stand or fall by the results in the near future. The amount of perchloride of mercury which is being daily used must be enormous. It must be understood that this wholesale disinfection has not been done while the outbreak was raging, but since.

The report contains many interesting tables of mortality and maps showing the localisation of the disease to certain parts of the city. I note an almost complete absence of the clinical aspects of plague. This is due to the absence of facilities for observation, practically no hospital being kept up by the plague authorities Neither is there any record of bacteriological work—probably for the same reason. In Major Deane's report I note an undertone of doubt upon the value of all bacteriological work with regard to plague. This is exceptional, but I trust that its influence will not be injurious. The volume before me is purely a record of plague administration and consists very largely of the work done in the way of disinfection. It is, perhaps, too early to gather the value of the scheme so recently adopted, but while a cleansing of the city must do good I do not feel so sanguine of the results as the main authors of this report. In fact, I find the chairman himself writing: "I am much afraid that all our efforts will not prevent the occurrence of a more serious epidemic than any yet experienced." There are many other points in the report to which it is hardly necessary to refer, as certain sections of all plague reports are more or less like each other. The influence of rats in the spread of plague is discursively dealt with at the end of the volume. I do not gather that any new facts have been observed but a general doubt is expressed as to their power of diffusing the disease. They are looked upon by the authors more as companions in trouble than as affecting the spread of infection to man. With the evidence obtained in other parts of the world I cannot subscribe to this view.

Taking the report as a whole it must be admitted that the subject matters taken up have been adequately treated. There are many points omitted, however, which might have been included.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Variations in the Incidence of Disease in Different Parts of India.—Objections to Some Statements on Plague Symptoms.—Military Rank or the Title of "Doctor."—Further Increase of Plague in India.

A RETURN of the various operations performed in the different provinces of India, and published by one of your Indian contemporaries, brings out the curious frequency of certain diseases in some parts and the rarity of the same diseases in others. Cataract, for example, so common in the North-West Provinces, and to a lesser degree in the Punjab, is comparatively rare in Madras. Stone, which is so frequent in the Punjab, is also rare in Madras. Hydrocele is a wide-spread disease in India and is said to be a common complaint—much more so than in Europe—but the returns show a peculiar infrequency in the Punjab. Obstetric operations are as frequently performed in Madras as in the other provinces, but cases of ovariotomy are exceptionally few. They are much more numerous in the North-West Provinces and the Punjab. Taking India generally I may add other differences to the incidence of disease as compared with the British Isles. Appendicitis seems to be extremely rare in India. On the other hand, hæmorrhoids are particularly common. Boils and carbuncles are much more frequently met with than at home. One writer in the *Indian Medical Gazette* says that they may be epidemic in character, that they are contagious from one person to another, that they are locally contagious from one part of the body to another, and that there is an infection of the house as shown by successive inhabitants being attacked. Acute rheumatism is very uncommon in India and cancer is not so frequent as in Europe. A recent investigation into the large amount of cases of fever following the famine shows that typhoid fever and Malta fever do occur amongst the natives of India. The occurrence of typhoid fever has been recognised for some years by the younger generation of practitioners, but is still accepted *with hesitation by the older school.*

Exception would probably be made by those in India who have had most experience of plague to some of the statements made by recent writers at home. It is stated, for example, that the most potent agent in the spread of the disease is undoubtedly contact with infected persons. This is not borne out in India, for the low contagious properties are recognised everywhere. Cases in one family or household are nearly always simultaneous or nearly so—not successive at intervals as if caught one from another. The percentage of cases among "contacts" is extremely small—less than 4 per cent.—and the occurrence of cases amongst friends and relatives visiting the sick in hospital is uncommon. Amongst native attendants it may almost be said to be rare. Then it is said that boils and carbuncles in plague are rare. While it is true that these complications vary at different places and in successive outbreaks their occurrence was by no means uncommon both in Bombay and Poona in the first two years of the epidemic. Again, it has been stated that suppuration takes place in and around the glands at an early date. This is quite incorrect. Breaking down and sloughing occur, but true suppuration is certainly delayed for a week, generally longer.

A recent article by Dr. Balfour Stewart of Liverpool treats among other matters upon the value of Lustig's serum in the treatment of plague. My previously expressed opinions and criticisms upon which you have permitted a long discussion in your columns are fully confirmed. Dr. Stewart had exceptional opportunities of judging while on duty in Bombay. The classification of plague into eight types is, to say the least, confusing. For all practical purposes the division into bubonic, septic, and pneumonic, is ample, and will include every case, so that to add nervous, toxic (or fulminant), puerperal, and two mild types is unnecessary.

A curious custom has gradually been adopted by the officers of the Indian Medical Service holding civil appointments and carrying on private practice in Calcutta in giving themselves the title of "Doctor" rather than that of their military rank. In most other places the surgeon has his rank stated on his name board, but in Calcutta Dr. —— without any other title is used. Possibly the gradual development of competition with purely civilian practitioners explains this custom.

There has been a considerable increase in the mortality from plague throughout India during the past week. The number of deaths given is 2943, an increase of 795 over that of the previous seven days. The disease is worse in the Bombay Presidency, 2663 deaths being recorded. Bengal returns 242 deaths, of which 11 occurred in the Sarun district.

Nov. 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Health of the County Palatine.

THE annual report of the medical officer of health of the county palatine (Mr. E. Sergeant) contains a regret that the gross death-rate (17 6 per 1000) does not compare favourably with the previous year, although it is below the county average *for the ten years* ending 1898. The increase in the death-rate is due to an increase in the number of cases of influenza and affections of the respiratory organs. The birth-rate shows a slight diminution as compared with 1898. Increased attention has been paid to the carrying out of sanitary work in the county, with the result that 37,866 nuisances have been abated in the districts. House-to-house inspection has been carried out systematically and 200 houses have been condemned as unfit for human habitation. Under the Sale of Food and Drugs Act, 1557 samples have been analysed, of which 195, or 12·52 per cent, were found to constitute offences against the Act. The report states that the Vaccination Act, 1898, has worked on the whole in a satisfactory manner, and there is no reason to fear a falling-off in the percentage of vaccinated children in consequence of the new provisions. With regard to slaughter-houses it is stated that on the whole they have been carefully inspected, but complaints are made by the medical officers of health as to the difficulty of supervising in a satisfactory manner private slaughter-houses. Mr G. H. Patterson, medical officer of health of Ulverston, says that "it is a great pity that vested interests should continue to stand in the way of the provision of public abattoirs which in every respect would be a decided improvement upon the plans which at present obtain." In a very interesting appendix Mr. Sergeant has dealt at some length with the question of the prevalence and prevention of tuberculosis with especial reference to the establishment of sanatoria. In order to understand the magnitude of the question as affecting Lancashire it may be stated that during the year 1899 the deaths from phthisis numbered 2305, and assuming that an average period of three years elapses from the reception of infection and death there is reason to believe that the persons affected with phthisis living in that year within the administrative county would be equal to three times the number of deaths, or from 6000 to 7000.

The Assize Dinner.

Among the guests at the recent annual assize dinner given by the Lord Mayor to the judges of assize was Sir William Mac Cormac, Bart., who defended in a vigorous speech, which was highly applauded, the administration of the Army Medical Department in South Africa.

A Memorial to Principal Oliver Lodge.

The plaster study for a bust in marble of Dr. Oliver Lodge, until lately professor of physics at University College, has just been completed. The bust, which has been commissioned by a number of Dr. Lodge's friends and admirers, will be placed in the hall or library of University College as a memorial of his association with the institution. Mr. C. J. Allen, a local sculptor, to whom the work has been entrusted has managed to effect a striking likeness of Dr. Lodge.

Poisoned Beer in Liverpool.

In common with Manchester and other places a scare has been caused in Liverpool with reference to cases of peripheral neuritis treated in the hospitals and supposed to have been caused by drinking poisoned beer. On Sunday, Dec. 2nd, the death occurred of a woman in the Mill-road Infirmary from alcoholic neuritis associated with symptoms of arsenical poisoning. The deceased, who had been a patient in the hospital for about a fortnight, had been a heavy beer-drinker. The deceased's urine was examined by Dr. Nathan Raw, the medical superintendent, and traces of arsenic were discovered. Two or three additional cases have occurred at the same institution, bringing up the total to a little over 60 cases treated at Mill-road. The result of the analyses of beer conducted by Dr. Campbell Brown at the instance of the health committee has led to the discovery that the arsenic present in the beer is traceable to the glucose sugar used at certain breweries. The Liverpool brewers are doing everything in their power to facilitate the work of the authorities in fathoming what seems to be a mystery. Some brewers, to their credit, rather than run any risk, have emptied large quantities of suspected beer down the sewers. In the cases of the samples of beer brewed by two or three brewers which have been analysed at their own request, Dr. E. W. Hope, the medical officer of health, has informed the brewers of the results of the analyses. Dr. Hope intends to embody all the results of his analyses in a comprehensive report which will be presented to the health committee at the earliest opportunity.

Dec. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Mr. H. E. Clark on the South African Hospitals.

MR. H E. CLARK, professor of clinical surgery at St. Mungo's College, Glasgow, who has recently returned from South Africa, delivered his presidential address at the last meeting of the Glasgow Medico Chirurgical Society and not unnaturally selected as his subject some of his recent experiences at the seat of war. He remarked at the outset upon the prominent part played by volunteers in rendering aid to the various departments of the army and more especially to the Army Medical Service. Among such volunteer efforts he claimed a prominent position for the Scottish Red Cross Hospital, of which he had had the honour to be senior surgeon. After a rapid sketch of his experience at Bloemfontein, which he reached immediately after the town came into the possession of the British, Mr. Clark proceeded to refer to the so-called hospitals scandal. Upon this subject he complimented the Director-General and his subordinates that in spite of the well-known fact that the Royal Army Medical Corps had been under-staffed with medical officers for years, and in spite also of the serious miscalculation which had been made at the commencement of the war as to the number of troops which would be required, the medical authorities had never failed to send out with each division of the army the recognised equipment of field, stationary, and base hospitals with a full complement of surgeons, nurses, and orderlies. The medical authorities it must be admitted, had not anticipated the terrible outbreak of enteric fever, which converted Bloemfontein in April last into a gigantic hospital camp. Even if they had expected this outbreak he doubted if much could have been done in the way of preparation. Obviously, it was impossible to set up hospitals in Bloemfontein before the town was in the hands of the British and it was equally impossible that general hospitals with their enormous equipment could accompany General French in his lightning march to Kimberley or in the subsequent advance on Bloemfontein. Hence the army entered the latter town with a large and constantly increasing number of cases of enteric fever having none but field hospitals for their treatment. It must be remembered that enteric fever was always present in towns in South Africa and it had been spread among the troops to a terrible extent by the men drinking the water of the Modder river which was so polluted that it was little better than liquid sewage. When the town was occupied the only communication with the main base at Cape Town was by a single line of narrow-gauge railway which was frequently destroyed in places by the enemy, who held possession of the country to the immediate south of Bloemfontein for fully a fortnight after the occupation of the town. It was amidst such transport difficulties that the medical staff had to work, their claims for material being necessarily second to the primary demand of the army for food and ammunition. Just as the conditions seemed to be improving came the crowning disaster of Sanna's Post which cut them off from the Waterworks and compelled them to fall back upon the wells in and around Bloemfontein at all times suspect but at that time more polluted than ever. Mr. Clark claimed that great credit was due to Surgeon General W. D. Wilson and his subordinates for what they accomplished under these trying conditions. Everyone admitted that many things were not as could have been wished, but if any fault existed this did not lie with the medical staff, the War Office, or the Government. It depended on the fact that war is war and could not be carried on without distress and suffering on the part of the whole army, in which the sick and wounded must needs participate. The state of matters which some critics would appear to demand would only be attained by sending general hospitals in advance of the army into those towns which were subsequently to be occupied—an obvious *reductio ad absurdum.* Many of the charges brought against the medical arrangements related to the base hospitals in the neighbourhood of Cape Town, where the difficulties of which he had spoken did not exist. But these charges had notoriously broken down, and it would be found when the report of the Hospitals Commission was issued that the hospitals at Wynberg, Rondebosch, and Woodstock had been cleared of the aspersions which had been cast upon them and that the work which they had accomplished had been great in amount and excellent in quality. Mr. Clark's address attracted a large audience who gave him a very cordial welcome on his return to Glasgow.

Dispensary Abuse in Glasgow.

The abuse of public dispensaries is an old grievance in this and other cities; lately, however, feeling in Glasgow has become so acute that the Southern Medical Society have considered it necessary to appoint a committee of their members to investigate the matter and, if possible, to suggest a remedy. There can be no doubt of the existence of this abuse of our infirmaries by those who are well able to pay a fee, particularly in the outdoor departments of the general hospitals and the special hospitals. It is understood that as it is the Southern Medical Society which has taken the question up, the Victoria Infirmary is the institution specially aimed at, and it is certain that in the south-western districts, supplied by that infirmary's dispensary, discontent and grumbling are very general among the younger practitioners. The question is one of great difficulty and it will be interesting to see whether the Southern Medical Society will be able to suggest a practically workable remedy. The suppression of the abuse complained of would not only benefit the practitioner, but would prevent the diversion of hospital funds into channels for which they were never intended by testators and subscribers, would lessen the pressure of the chronic poverty of our infirmaries, and would enable such institutions to accomplish more work among the deserving poor.

Dec. 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Joseph Radford Cardiff, M.D. Glasg., L.R.C.S. Irel., Coroner for South Wexford.

THE death of this well-known and highly esteemed country physician took place on Nov. 19th at his residence Carrigbyrne, near the town of Wexford. Dr. Cardiff was an M.D. of Glasgow and a Licentiate of the Royal College of Surgeons in Ireland. He filled the office of coroner for the Southern Division of County Wexford for many years, and was widely known as an active practitioner until four months ago, when a severe attack of gout, from which disease he had suffered periodically for many years, confined him to his house. His death will be much felt over the wide country district to which his practice extended.

The Coronership of South Wexford.

The vacancy in the coronership of South Wexford caused by the death of Dr. J. R. Cardiff, is about to be filled, one of the candidates being the Nationalist Member of Parliament for the division. If Mr. Ffrench be elected it is understood that he will resign his seat in the House of Commons in favour of Mr. T. D. Sullivan, a well-known Nationalist recognised as the Poet Laureate of political Ireland.

Health Lectures at Queen's College, Belfast.

In accordance with the requirements of the founder of the chair of Physiology in Queen's College, Belfast, Professor W. H Thompson is giving a series of popular lectures on the Nervous System: its Functions and their Relation to Health. They commenced on Nov. 28th and are fully illustrated.

Annual Dinner of the Ulster Medical Society.

The annual dinner of this society was held in the Prince's Restaurant, Belfast, on Nov. 24th. The President (Professor W. H. Thompson) occupied the chair and there were between 50 and 60 members present. The guests were: the President of Queen's College, Belfast, the President of the North of Ireland Branch of the British Medical Association (Professor J. W. Byers), the Right Hon. the Lord Mayor of Belfast (Sir R. J. McConnell, Bart.), Professor Rubert W. Boyce (University College, Liverpool), and Lieutenant-Colonel R. G. Thomsett, R.A.M.C. After an excellent dinner had been served, the President proposed, in very happy terms, the toast of "The Queen," which was received with great loyalty. Dr. J. Walton Browne gave the "Navy, Army, and Reserve Forces," to which Lieutenant-Colonel Thomsett, principal medical officer of the Belfast district, replied. Professor J. Symington proposed the toast of "The City and Trade of Belfast," which was responded to by the Right Hon. the Lord Mayor. "The Queen's College and Belfast Medical School" was proposed by Professor Rubert Boyce of University College, Liverpool. The President of Queen's College and Professor T. Sinclair replied. Dr. W. A. McKeown proposed "The British Medical Association," to which Professor Byers, President of the North of Ireland Branch, responded. "The Health of the President of the Ulster Medical Society," which was a toast received with the utmost enthusiasm, was proposed by Dr. W. Calwell. Professor Thompson having replied, Dr. James Colville gave "The Health of the Honorary Secretary," to which Mr. Robert Campbell, responded. During the evening excellent recitations were given by Dr Andrew Fullerton and Dr. J. S Morrow, and, through the kind introduction of Dr. J. St. C. Boyd, one of the prominent supporters in Belfast of the Feis Ceoil, a well-known Irish piper, Mr. R. L. Mealy, gave two excellent musical contributions. Altogether the banquet passed off most successfully.

Death of Reuben Bolton, M.D. R.U.I., J.P.

I regret to announce the death of Dr. Reuben Bolton, J.P., of Bangor, Co. Down, which took place suddenly on Nov. 20th. Shortly after 1 P.M. on that day he was discovered in an unconscious condition in the hall of the dispensary in Bangor, where he had gone to prepare medicines which some of the dispensary patients were to call for. During the morning he had attended to his duties as usual, having visited three patients, including a maternity case, before proceeding to the dispensary. He had for some time been suffering from heart disease and some four months ago he had a serious seizure from which he seemed never to have recovered thoroughly. Born in Dungannon Dr. Bolton entered Queen's College, Belfast, where he was a most distinguished student and scholar. He graduated M.D. of the old Queen's University in 1865. For a time he practised in Belfast, but going to Bangor 25 years ago he was in 1878 appointed medical officer of the Bangor district of the Newtownards Union. He was also medical officer to the Royal Irish Constabulary and surgeon to the Bangor Cottage Hospital. He took a great interest in Masonic affairs. He was a magistrate for Co. Down. Genial in his manner, kind to his patients, and of a most sociable disposition, Dr. Bolton was greatly liked. He leaves a widow and four children, three girls and a boy. He was buried on N[illegible] 22nd.

Dublin Medical Students.

The anatomical returns of students who have entered for dissection have been made up to Nov. 25th, 1900. The total shows a falling off of one as compared with the returns of last year—viz., 422 as against 423.

Cork Hospital Saturday Fund.

The Cork Hospital Saturday collection was a distinct success this year A new feature was the inauguration of local collections in two of the county towns—viz., Bandon and Midleton—where the amounts received were very satisfactory. Last year no street collections were made, but this year, owing to the energy displayed by all concerned, the amount realised was nearly double that collected in the year 1898 At a meeting of the committee held last Friday the honorary treasurer's statement showed that the total amount available for distribution was £976. It was allocated as follows:—North Infirmary, £195; South Infirmary, £195; Mercy Hospital, £141; Women and Children's Hospital, £78: Cork Fever Hospital, £78; Eye, Ear, and Throat Hospital, £74; St. Vincent's Hospital for Women and Children, £58; St. Patrick's Incurable Hospital, £57; Lying-in Hospital, £50; Cork Maternity, £50. Votes of thanks were passed to the ladies who had made the street collections, to the several officials of the committee, and also to the Lord Mayor and Lady Mayoress. There is no doubt that his lordship and the Lady Mayoress by their whole-hearted zeal contributed largely to the very gratifying success of this year's collection.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Drinking-water Question.

THE question of the Paris supply of drinking-water has entered on a new phase. In reply to the cogent arguments of the Academy of Medicine, of the Committee of Hygiene, and of the learned societies, the authorities of the municipal water-supply have hitherto put forward nothing but promises and announcements of great works to be carried out at some future date, which, however, would without doubt satisfy in every particular the medical men. The only thing was that these magnificent projects either never came off or else were carried out in a very different style from that which had been agreed upon. To put the matter shortly, the engineers acted exactly as they thought fit while hiding their rebellion under a pretence of fine words. They have now given up even a show of agreement with the medical authorities and have declared open war. The Prefect of the Seine, in replying to the resolutions passed by the Academy of Medicine, has met them with a flat denial and the engineers proclaim for the future their pretence of insuring the water-supply of the city without paying the slightest attention to the views of the Academy of Medicine or to those of the professional hygienic authorities. This is how the matter came to a head. The "water lords" (*administration des eaux*), instead of finding new springs, found it much simpler to construct, near Paris, filtering beds into which water from the Seine should be led. This water after passing through beds of sand and gravel passes into reservoirs from which it is distributed to people as drinking-water at times such as when the spring water-supply fails. This, of course, is during very dry weather and it is precisely then that the Seine is lowest and consequently most befouled and its water most difficult to render fit for drinking by any filtration process. In my letter published in THE LANCET of Nov. 24th, p. 1538, I gave your readers an account of how this custom was criticised by the Council of Hygiene and of the confession which the chief engineer had to make how during a period of three weeks during this summer Seine water was mixed with spring water and that the period of admixture coincided with a recrudescence of typhoid fever. The Academy of Medicine in its turn has sent a resolution to the Prefect of the Seine setting forth that the necessary measures ought to be undertaken without delay for insuring a complete separation between spring water and filtered river water, and moreover that the water of the Seine should be supplied at such a pressure that it could be used by the inhabitants of Paris for such purposes as lifts, washing, and watering. Owing to the low pressure at which the river water is supplied spring water has to be used for these purposes. The Prefect's reply is simply amazing. According to him spring water and filtered river water have been for a long time delivered by quite separate services. He refuses to use the filtered Seine water as the Academy demands for industrial purposes and this for a most remarkable reason—namely, because the filtration necessitates a series of delicate and difficult operations which would, if the water were used for industrial purposes, simply result in a loss. He might just as well argue that the "water lords," having already made a grave mistake in adopting this gross method of filtration in face of the protests of the Academy and the Council of Hygiene, suggest that the water should be used so that the expense to which they have been put for purification should not be wasted. The defence of the water from an alimentary point of view is undertaken as follows. The filtered water, says the Prefect, has been certified as being perfectly wholesome in numerous analyses made by the chemists of the official laboratories, and contains, as a matter of fact, fewer bacteria and less organic matter than does spring water. The whole of suburban Paris and many large cities, notably London and Berlin, are supplied with filtered river water for drinking and the public health does not thereby suffer. In fact, adds the Prefect, the mortality in cities so supplied is no higher than in cities supplied with spring water. As for supplying river water at high pressure the Prefect ignores this question entirely on the ground that it is concerned with technical and administrative details with which the Academy of Medicine has nothing to do. The Academy naturally protests vehemently against this high-handed way of treating its resolutions, and M Henriot has again lifted up his voice against the assumption of the engineers that Seine water is fit for drinking. In the present state of bacteriology a bacteriological examination is not enough to affirm the purity of a water, and nothing is more dangerous than to rely on laboratory researches, however numerous they may be. Typhoid fever possesses an organism which reacts much more delicately to it than any organism known in the laboratory—namely, the human body—and the people of Paris would have been spared the sad experience of the last two years if the prefectoral administration had seen fit to forbid absolutely the admixture of river water and spring water. M. Henriot concluded by deploring the pig-headedness of the engineers, by sticking to their system, in compromising the interests of public health and rendering of no effect the enormous sacrifices which the city of Paris has made to keep itself free from typhoid fever. M. Brouardel agreed with him. The debate concluded by the appointment of a committee charged to lay before the Prefect of the Seine the resolutions of the Academy in a yet more urgent form.

Penetrating Gunshot Wounds of the Cranium.

The Society of Surgery has again had this subject under consideration. Opinions were much divided. With reference to the use of the x rays for diagnostic purposes M Tuffier considered that these rays should not be used directly after the infliction of the injury. M. Reynier, on the other hand, thought that they could be used with safety without delay, and that by the use of M. Contremoulin's arrangement the position of projectiles could be easily located. As for treatment there were two main currents of opinion—one in the direction of simply enlarging the wound of entry, removing fragments and making the trail of the bullet aseptic, but not searching for it unless there were grave cerebral symptoms; the other view looked upon the bullet itself as a septic body and that it should be removed, if possible, as long as it lay within easy reach.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Question of Priority in the Mosquito-Malaria Theory.

THE *Policlinico* of Nov. 1st, in publishing a letter from Major R. Ross, I.M.S., on this subject, says by way of preface that "scientific discoveries do not usually gush forth ready-made from the mind of genius, but are the fruits of the activity of many energies which unite the elements more or less directly serviceable to attain the desired end. Whether the greatest credit is due to him who initiates the work, or to him who prosecutes it most successfully, or to him who synthesises and presents it in the best form, is always a subject of discussion in regard to everything new. No wonder, then, that such a dispute should arise around a doctrine so important both in its scientific bearings and its immediate practical application as that which aims directly at the reclamation from malaria and utilisation of immense tracts of territory hitherto waste. The *Policlinico* is glad to open its columns to such questions and to men of such worth. No preconceived scientific opinions, neither personal considerations, nor a blind patriotism, nor servility towards foreigners will hinder it from keeping the controversy to the region of facts." It is indeed no more than fair that the Italian scientific world, which has hitherto heard only one side of this question, should now get the opportunity of hearing the other and so be in a better position to apportion merit to those who deserve it. Major Ross has many complaints against Professor Grassi, who, he says, in his recent work, "Studi di un Zoologo sulla Malaria," seeks to discredit the former's researches on malaria in order to gain unmerited credit for himself. Major Ross thinks that many persons in Italy who are not acquainted with the true facts may be misled by these plausible statements of Professor Grassi which he characterises as a tissue of disingenuous fallacies and a contortion of the facts with omissions of dates and attacks upon his (Major Ross's) veracity. He then recalls the different steps in his work dating from May, 1895, his first unsuccessful attempts to cultivate the parasite in culex, followed in August and September, 1897, by his success with semilunar-bodies in anopheles; the interruption of his experiments at this point and their resumption a year later when he successfully demonstrated the extra-corporeal life-cycle of hæmosporidia of birds in mosquitoes and infected healthy birds experimentally by means of the bites of these insects; and finally, after a second interruption of his labours, the publication of his results by Manson and himself on June 18th, 1898—a date a month in advance of the time at which Professor Grassi, by his own account, commenced his work on the relation between malaria and mosquitoes, and fully four months before he and his colleagues could show any result. And this success they only obtained by following Major Ross's methods and profiting by his observations, previously to which Professor Grassi and his friends had been lost in a maze of error. Even Professor Grassi's pretence that Major Ross had not indicated the anopheles as the definitive host of the parasite falls to the ground, for he himself had evidently recognised it from Major Ross's description of his "dapple-winged mosquito," as appears from several circumstances, but more especially from a letter dated Nov. 25th, 1898, written to Major Ross by Dr. Charles of Rome, in which the latter states that he had found Professor Grassi in his laboratory intently reading Major Ross's letter to the

British Medical Journal of Dec. 18th, 1897, and that Grassi appeared to be convinced that the description of the mosquito therein given referred to the anopheles claviger. Indeed, a few hours afterwards, according to Dr. Charles' Professor Grassi found some of the zygotes derived from semilunar bodies in the anopheles claviger. It is absurd, then, Major Ross contends, for Professor Grassi to arrogate to himself the merit of the original discovery simply because he had confirmed it. In conclusion, Major Ross appeals to the recognition accorded to him in the matter of priority by such authorities as Laveran and Blanchard in France, by Koch in Germany, by Manson and Nutall in England, by Celli in Italy, and by the *Indian Medical Gazette* in India.

Medullary Anæsthesia.

At the second sitting of the Italian Surgical Society a discussion was opened by Dr Fummi on Bier's method of cocainising the spinal cord, by a reference to 40 cases operated on under Professor Montenovesi's direction at the Santo Spirito Hospital. The point he wished to dwell upon was the attempts to extend the anæsthesia to the higher parts of the trunk and to the upper extremities. By experiments on dogs and on the cadaver it was sought to determine why a liquid of the specific gravity of 1014 (which is nearly that of the ordinary 1 per cent. solution of cocaine) cannot ascend to the upper portion of the spinal cord even when the body is placed in a strongly inclined attitude head downwards. It appeared that the reason lies in the difference of specific gravity between the cocaine solution and the cerebro-spinal fluid. By using a solution of cocaine in glycerine the alkaloid was found to reach the highest point of the cerebro-spinal canal, being detected by the very delicate method of Grefel even in the cerebral ventricles. This was still better seen with solutions of methyl blue in glycerine. The first application of this glycerine solution of cocaine to the human subject was followed by distinct anæsthesia of the thorax, neck, and upper limbs. Immediately after the injection the patient was placed in the inclined position and he soon began to experience a sensation of formication and heat advancing from the abdomen to the thorax and thence to the neck and arms. Further observations will be reported later; meanwhile, the trials are being continued in Professor Montenovesi's wards. Bastianelli and Fioretti related their experience of this method of anæsthesia, the former from a total of 35 cases, the latter from 25 cases. Bastianelli gave as cases suitable for its employment operations on the lower extremities, laparotomies, and uncomplicated hernias; and as contra-indications, the need for full muscular relaxation, nervousness, the age of infancy, extensive abdominal operations (on account of the sensitiveness retained by the peritoneum), states of collapse, &c. On the whole, the discussion showed that the method is taking up a recognised place here, and that the variety of surgical procedures in which it may be employed is rapidly increasing.

Dec. 1st.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Politics and the Profession.

A GOOD many members of the medical profession have been returned to Parliament in the recent general elections held on Nov. 7th, and some notable ones have fallen in the fight Amongst these is the venerable and virile leader of the Conservative party, Sir Charles Tupper, who has since announced his retirement from public life. At the age of 34 years, Sir Charles, then Dr., Tupper forsook a lucrative and growing practice in his native province of Nova Scotia for politics, and rapidly attained a commanding position in the councils of his country. At Confederation in 1867 he took a prominent part in the formation of the Canadian Medical Association and was unanimously elected its first president, which office he successfully filled for the two succeeding years. At the age of 80 years he has exhibited in the recent campaign a wonderful vitality, and his loss will be a keen one to the Conservative party as well as to the country. In many public works, this Canadian practitioner has left his lasting mark. The profession throughout the Dominion is congratulating itself that Dr. T. G. Roddick, the promoter of the Dominion Medical Council Bill, has been able to retain his seat in Parliament by a narrow majority. Speaking recently at a banquet tendered in his honour Lord Strathcona paid a high and deserving tribute to Dr. Roddick for the good he was seeking to accomplish in bringing about this Dominion registration, stating that the public were beginning to take an interest in the measure, as it would be another means of knitting the provinces together in closer bonds of union. The medical profession can now look forward confidently to important progress being made in this direction at the next meeting of the Dominion Parliament.

Vital Statistics in Ontario.

By the returns last year from the Registrar-General's office for the province of Ontario the birth rate was shown to have decreased considerably as compared with the previous year. At that time it was thought that the apparent decrease might be due to defective returns, so an extra effort was put forward to remedy this laxity on the part of parents, but the returns for 1899 exhibit a still further decrease. The births in Ontario last year (1899) numbered 44,705 as compared with 46,599 in 1898, a decrease of 1894. On the other hand, the marriages exceeded those of the previous year by 1139, the figures being 16,514 as compared with 15,375 in 1898. The deaths for 1899 number 28,607, as against 26,370 in the preceding 12 months, or an increase for the former period of 2237. The birth-rate was 19·4 per 1000 in 1899, as compared with 20·4 in 1898; the death-rate was 12·4 per 1000, as against 11·5; and the marriage-rate was 7·1 per 1000, compared with 6·70.

Toronto General Hospital Training School for Nurses.

The annual graduating exercises of this institution were held on Nov. 9th, when 13 graduates received their diplomas. This institution was established in 1881 with 16 pupil nurses, and since that time 317 have graduated, 223 of whom are still actively engaged in the practice of their profession, many of these being employed in the neighbouring Republic, as Canadian nurses are much sought after by the hospitals of the United States. A new and handsome residence has just been completed for the nurses, of whom there are now eight probationers and 59 pupil nurses, at a cost of £4000 ($20,000) which is the finest of its kind in the Dominion. The lady superintendent stated that during the past year she had received 650 applications, of which only 25 were granted. The course of training in the school lasts for three years and during that time a pupil nurse receives $4, $5, and $6 per month respectively, board and washing being also supplied.

Home for Incurable Children, Toronto.

This deserving institution was started in September, 1899, when Senator Cox presented the lady philanthropists who were undertaking the work with a fine house in a residential quarter of the city for a home. In December last this was formally opened with the reception of two little patients. At the first annual meeting held a few weeks ago the secretary's report showed that during the past year 13 children had been admitted, and of this number 10 now remain, two having died and one having been transferred to the Orillia Asylum for Idiots.

The Consumption Sanitarium for Toronto.

Toronto is making an earnest effort to establish a sanitarium for her consumptives. The medical health officer, Dr. Sheard, has just reported on the subject to the effect that as soon as the Anti-Consumptive League of Ontario or the National Sanitarium Association, which controls the Muskoka Cottage Sanitarium, provides a fund of $50,000, the city should submit a by-law to the ratepayers for authority to contribute a like sum. Dr. Sheard further stipulates for the city that the institution must be located within 30 miles of the city and that the grounds surrounding the same must not be less than 50 acres in extent. Mr. Gage, the treasurer of the national organisation, who was instrumental in founding the Muskoka Sanitarium, has now come forward with an offer to construct and to equip the hospital at the expense of the National Sanitarium Association without any civic assistance. The offer of Mr. Gage is for a hospital of 50 beds, and it is altogether likely, now that conditions are in such good shape, that the city of Toronto will soon have its consumptives properly looked after.

The Victorian Order of Nurses

A meeting of the board of management of the Victorian Order of Nurses was recently held in Montreal and amongst others present were Lord Strathcona, who has given considerable monetary assistance to the Order, and Dr. Craik, Dr.

Stewart, and Dr. Adami, who have ever taken a deep interest in the welfare of this charity. The report of the secretary showed that during the past summer, although the staff for nursing was small, in the city of Montreal over 2000 visits had been made. Professor Bovie read the report of the work throughout the Dominion, which showed that 25 branches had been established in Canada with a staff of 30 nurses, who had attended to over 700 cases during the past year.

Medical Banquets.

Bishop's College, Montreal, and Trinity Medical College, Toronto, have recently held their annual banquets. At Bishop's College Dr. Wolfred Nelson of New York, who was the first student to register on the books of the College, was present and replied to the toast of "Alma Mater." At the Trinity banquet the venerable Dean, Dr. W. B. Geikie, replied to the toast of "Trinity Medical College," speaking of the good work which Trinity had performed in the medical world. 1300 students had left her doors during the 30 years of her existence, some of whom were located in all parts of the globe and many of whom were now occupying positions of prominence in the United States and in Canada. Of her present faculty all but three of the 27 were her graduates. The Dean also exhibited a copy of the first Register—a slip of paper which looked somewhat the worse for wear—and the first set of examination papers, as well as the first annual announcement of the college, which, at that time a mere card, has now attained to the respectable proportions of a handsome calendar of more than a hundred pages. Referring to the war in South Africa he said that Trinity had done nobly for Canada in that respect, as the following list attests: Dr George Stirling Ryerson, Canadian Red Cross Commissioner; Dr. Barrie, representative of the Young Men's Christian Association; Dr. Leonard Vaux (son of the President of the Provincial Board of Health of Ontario); Dr. Lea, Dr. Worthington, Dr. Brennan (who had been Mr. Kruger's physician until hostilities broke out and who immediately joined the British army), Dr. Farrell, and Dr. Irving, and Mr. Archie Anderson, Mr. W. J. Macdonald, and Mr. W. T. Robertson (students), as well as Lieutenant Temple, son of Dr. Temple, professor of obstetrics and gynæcology in Trinity Medical College. In addition there was Dr. H. Roberts of Sheffield, England, a graduate of 1896. Trinity, the Dean thought, could well afford to be proud of her contribution to the war.

National Sanitarium Association.

The annual meeting of this association was held in Toronto on Nov. 3rd, and in the absence of the President, Lord Strathcona, Sir William R. Meredith, Chief Justice of Ontario and Vice-President of the association, presided. The third annual report was presented, which showed the work done at the Muskoka Cottage Sanitarium for the past year. It is now three years since this institution was opened and the yearly results have been of the most gratifying character. During the three years 371 patients have been received, 47 of whom are still under treatment. The number discharged, apparently cured, has been 57; with marked improvement, 78. The average stay of each patient has increased each year, and this year has increased to 129 days. At the beginning of the past hospital year, on Oct. 1st, 1899, there were 48 patients remaining, and during the year 141 more have been admitted, making a total on the books of 189.

Toronto Clinical Society.

At the monthly meeting of this society, held on Nov. 14th, Dr. Graham Chambers showed an interesting case of Alopecia Universalis in a young woman, aged 20 years, exhibiting total absence of any hairs whatever, except two on the anterior portion of the scalp. The same condition had occurred when she was five years of age, but she recovered at that time. Two years ago she had suffered from interstitial keratitis.—Dr. George A. Peters exhibited interesting specimens from a Hydatid Cyst of the Pancreas which he had removed from a young man from the Argentine Republic. A tumour could be felt below the left ribs midway between the nipple and sternal lines. It was diagnosed as being connected with the pancreas, as resonance was easily determined between the tumour and other organs. such as the left lobe of the liver, the kidney, and the spleen. Dr. Peters said that there was no doubt of its being connected with the tail of the pancreas. The patient had had indefinite pains in the region of the stomach for two or three years with subsequent removal of the appendix vermiformis. Hooklets obtained from the fluid were shown under the microscope. A few weeks before the operation was performed the cyst had been tapped and 20 ounces of fluid had been extracted of a specific gravity of 1013. The operation was performed from behind through an incision three inches in length along the erector spinæ. A search of the literature so far by Dr. Peters reveals no other reported case of hydatid cyst of the pancreas.

Toronto, Nov. 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Work of the Life Savers.

THE general superintendent of the Life Saving Service in the United States reports that at the close of the fiscal year the establishment embraced 269 stations, 194 being on the Atlantic, 58 on the lakes, 16 on the Pacific, and one at the Falls of the Ohio. The number of disasters to documented vessels within the field of operations of the service during the year was 364. There were on board these vessels 2650 persons, of whom 2602 were saved and 48 were lost. 673 persons shipwrecked received succour at the stations, to whom 1447 days' relief in the aggregate were afforded. In addition to the foregoing there were during the year 329 casualties to small craft, such as small yachts, sailboats, rowboats, &c., on board of which were 781 persons, of whom five were lost. Besides the number of persons saved from vessels of all kinds there were 595 others rescued, who had fallen from wharves, piers, and other positions of extreme peril, many of whom would have perished without the aid of life-saving crews. 514 of these were rescued from dwelling-houses, outbuildings, and other elevated places, submerged wholly or in part by the terrible flood of the Brazos river in Texas, July 6th to 12th, 1899. The investigation made into the details of every shipwreck involving loss of life and into the conduct of the life-saving crews shows that no life was lost through lack of prompt and faithful efforts on the part of life-saving men. More than half of those who perished were lost by reason of their unwise attempts to reach the shore in their own boats instead of remaining on the wrecks. The general superintendent calls attention to the justice and necessity of an increase in the compensation of district superintendents, who, he believes, are the most poorly paid servants of the Government, considering the nature and extent of their duties and their heavy financial responsibilities, and he makes a strong plea in their behalf.

Gunshot Wounds in 1898–1899.

The Surgeon-General of the United States Army in his annual report reviews the results of gunshot wounds during the war with Spain. Of the 4919 men injured by gunshot during the years 1896 and 1899, 586 were killed and 4333 were wounded and received into the field and other hospitals. The killed constituted 11·9 per cent. of those struck and the wounded 88·1 per cent. In other words, one man was killed for every 7·4 wounded. The Mauser bullet must therefore be regarded as less deadly than the larger missile used during the Civil War. In percentages the casualties were: killed, 17·97; wounded, 83 03; or one man killed to every 4·56 wounded. The relative proportion of killed was therefore considerably larger during the Civil War than during our recent experiences. It is to be noted also that many of the wounds of the past two years were made by missiles of larger calibre. Of those reported in 1899, 471 were especially stated as having been caused by the Remington bullet of calibre 0·45. It is safe to say that had the whole number of wounds received been inflicted by the smaller Mauser or Krag-Jorgensen bullet the percentage of immediately fatal wounds would have been materially lessened. The character of the injuries inflicted by the modern bullet is manifested also when we exclude the killed and regard only those wounds which came under the care of the surgeons. Of these during the two years there were 4333, and 259 of the patients, or 6 per cent. of the whole number, died. The corresponding percentage from the records of the Civil War was 14·3. The marked reduction of the ratio of killed to wounded may be placed to the credit of the small-calibre bullet, but due credit must be given to the improved surgical methods of the present day. Wounds of any region of the body may be taken in comparison and the result will always be found to show a decided lessening in the percentage of cases ending fatally among those of the past two years as compared with those of the Civil War. Take, for instance, gunshot wounds of the femur. Of 6576 fractures of the femur during that war, 2923 cases were treated by primary amputation, 186 by resection, and the remaining 3467 by conservative or expectant measures. The limb was promptly amputated in 44 4 per cent. of the gunshot fractures. On the other hand, during the past two years 82 cases of gunshot fracture of the femur were reported, six of which were treated by primary amputation and two by resection, the remaining 74 cases being treated by conservative methods, not because the conditions were not favourable for the performance of primary operations, but because of the conviction that under present methods of treatment the limb could be preserved without adding materially to the danger of life. The limb was lost through surgical intervention in only 7·3 per cent. of the cases. Not only limbs but lives were saved by the surgical practice of the past two years. The mortality varied from 4 3 per cent. of cases in which the lower third was fractured to 15·6 per cent. of the cases in which the upper third was the site of the injury, whereas the corresponding percentages of fatal cases during the Civil War were respectively 42·8 and 49 7. The whole of the lessened mortality in these serious fractures may be credited to the protection given to the wound by the first-aid dressing and to the care exercised in the subsequent aseptic treatment of the fractured limb. In penetrating wounds of the thorax the rate of mortality fell from 62 6 per cent. during the Civil War to 27 8 per cent. during the years 1898 and 1899. During the Civil War there were 3475 penetrating wounds of the abdomen in which the ultimate results were determined; 3031 of these, or 87 2 per cent. of the total, proved fatal. During the years 1898 and 1899 116 cases, 81 of which were fatal, were recorded, the fatal cases constituting 70 per cent. of the total. Of 10 cases in which laparotomy was performed 9 were fatal. The alteration in the percentages of mortality in fractures of the cranium is less marked than in wounds of other parts of the body Of 4243 cases of cranial fracture during the Civil War 2514, or 59·2 per cent., were fatal. In 1898 and 1899 68 cases were recorded with 37 deaths, the latter forming 54 4 per cent. of the whole number.

The Insane of Cuba.

The population of Cuba is 1 500,000, and the number of insane in custody is 424, making the proportion of insane to population three to every 10,000 inhabitants The Secretary of State is the chief supervising officer, but there is a board of management consisting of six members. A medical director is the chief executive officer of the asylum. He states that the equipment is in every way defective and will have to be changed. Everything accomplished in the United States and Europe by modern science in the hospitals and institutions for the insane is quite unknown in Cuba. Every rule of hygiene is defective or completely lacking and this constitutes a source of danger which should be overcome at once, and in addition to this most of the buildings are on the point of tumbling down. There seems to have been no effort made thus far to classify the insane and no separation has been possible between the quiet and violent, and the several social classes are all mixed together. But an effort is now being made to better the existing conditions and the United States is asked for an appropriation for the improvement of the hospital.

The Cost of Crime.

It appears from the studies of the Secretary of the Prison Association that in New York City during 1899 items wholly due to crime cost the Public Treasury nearly $13,000 000 and items partly due to crime $8 000,000, a rate of about $6 per capita of the population. The per capita cost in San Francisco was about $5; in other cities it was from $3 to $3 50. In rural districts a conservative estimate would be about $1 per capita. The total cost of crime in the United States is estimated at $150,000,000 for cities and counties and $50 000,000 for States and the nation. These figures, uncertain as they may be, prove that crime is by far the largest factor with which political economy has to deal The only other item of expense which comes near it is the maintenance of public schools, which for the same year aggregated about $139,000 000 But the enormous expenditure mentioned above is only for the prevention of crime; no possible statistics can be compiled to give an estimate of the cost of property stolen and the suffering caused by crime. $1600 per year is a conservative estimate of the amount of money stolen by the average habitual criminal. There are at present 100,000 prisoners in confinement, of whom from 40 to 50 per cent. are habituals, but this does not represent the cost of drunkenness or the cost of crime which is never detected. The total of all items of expense chargeable to crime amounts to $600,000,000 per year, which exceeds the value of the wheat or cotton crop.

A New Emergency Ration.

Official tests are being made of the value of three different emergency rations; these tests are made by a board of army officers appointed for the purpose. Two of these rations are proposed by manufacturers and the board has offered one of its own. The latter consists of three cakes of meat and cereal compound and two cakes of sweetened chocolate. The total weight of these concomitants is 16 ounces, besides three-fourths of an ounce of salt and one gramme of red pepper; of the other ingredients the chocolate weighs four ounces and the meat and cereal in combination respectively four and eight ounces. A flask-shaped can contains the ration and this is hermetically sealed; its edges are rounded, and it is six and a quarter inches long. A key accompanies the can by which it may be opened. The plan is that this ration shall be part of the regular outfit of the soldier in field service, and the important point to be settled is whether it contains sufficient quality and quantity and will not sicken when it is the sole dependence A trial has been made in a long march and at the end of this test it was found that no soldier had lost flesh. The march was across the Indian reservations of several of the western tribes, and though it seemed rather hard for the men to get accustomed to it at first they grew to enjoy the ration.

Nov. 18th.

Obituary.

THOMAS FREDERICK HALE, M.R.C.S. ENG., L.S.A.

MR. THOMAS HALE of Barrow Hill, Chesterfield, Derbyshire, died at his residence there on Nov. 4th, in his seventy-fourth year, after a long illness. On Feb. 17th, 1898, he was seized with symptoms of cerebral hæmorrhage followed by right hemiplegia. His speech was slightly impaired, but his faculties were as clear as usual. During the whole of his illness he never left his bed. Mr. Hale was the son of the late Mr. Thomas Hampton Hale, a surgeon at Petworth, Sussex. He received his medical education at Guy's Hospital and took the diplomas of M R.C S. Eng. and L S.A in 1853. He at first practised in South Wales, but in 1859, through the late Mr. Richard Barrow, at that time owner of what is now the Staveley Coal and Iron Company, he moved to Barrow Hill and became surgeon to that company, an appointment which he held until his death. He was also surgeon to the Midland Railway Company and to various societies. Below the medium height, somewhat portly, with a strikingly handsome face, a pleasing smile, an urbane manner, hospitable and courteous, he was much sought after socially. He was exceedingly fond of music and possessed a rich clear tenor voice. Warm-hearted and generous, a loving husband and father, and a kind friend to the poor, he has left in the hearts of those who knew him a memory that time will not easily efface Mr. Hale is survived by his widow, four sons, and four daughters.

THE LATE PROFESSOR A W. HUGHES.—At a largely attended meeting of members of the medical profession held in Cardiff on Nov. 24th it was decided to raise a fund for the endowment of an anatomical museum in the medical school of University College, Cardiff, and also that a medal should be awarded annually in the medical school as a memorial to the late Professor A. W. Hughes. About £360 were promised for the purpose. At a meeting of townspeople held in Cardiff on Nov. 30th it was decided to support the fund being raised to perpetuate the memory of the late Professor Hughes It was stated that a sum of £1500 would be required for the purpose and several donations were promised, including £50 from Lord Tredegar.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

The Council resumed its sittings on Thursday, Nov. 29th.

The most important business (in some ways) of the Session occurred on that day, when Dr. Henry Ward Irvine, consulting physician to the Birmingham Consultative Medical and Surgical Institution, was summoned, at the instance of the medical staffs of the General Hospital and Queen's Hospital in Birmingham, to answer a charge of professional misconduct in allowing his name to appear in sundry advertisements. Dr. A. G. Bateman, for the Medical Defence Union, formulated the charge against Dr. Irvine. The charge was proved to the satisfaction of the Council, who gave Dr. Irvine until the session of next May to reconsider his position.

The Council, on Friday, Nov. 30th, received from the Pharmacopœia Committee the completed draft of the Indian and Colonial Addendum to the British Pharmacopœia. For this work the Pharmacopœia Committee is largely indebted to the late Professor D. J. Leech, Dr. Tirard, Mr. W. Kirkby, Mr. E. Morrell Holmes, and especially to Professor John Attfield, who has given 14 years of loving servitude to the completion of the British Pharmacopœia. The whole profession will endorse the special vote of thanks awarded by the Council to Professor Attfield. The text of the Addendum which has been sent to us will be reviewed next week.

On Tuesday, Dec. 4th, there was resumed the debate, adjourned from May 31st, 1900, on the position of the Royal College of Physicians of London and the Royal College of Surgeons of England in the face of the report of the Education Committee of the General Medical Council upon preliminary scientific education. The contest between the Colleges will not, we hope, go much further. The Council has shown an unmistakeable intention to stand by its position and, in spite of the able pleas of Sir Dyce Duckworth and Mr. Bryant on behalf of their respective corporations, we think the Council is right to expect deference. But what will the Council do if it does not get deference? If it proceeds to law who will pay the bill? Every possible chance of peaceful solution of the difficulty must be tried.

On Wednesday, Dec. 5th, the Council was sitting *in camerâ* for some time. The public proceedings commenced with a debate upon the examination of the Apothecaries' Hall of Ireland. Mr. Tichborne pleaded for certain omissions in the report on the inspection of the October examinations, but Sir Dyce Duckworth, speaking as chairman of the Examination Committee, argued, and carried the Council with him, that the report should be printed in its entirety. In the course of the debate Dr. McVail raised an interesting point of law. Mr. Tichborne was claiming for the Society of Apothecaries of Ireland certain privileges under an ancient Act of Parliament when Dr. McVail asked, on a point of order, whether the Council had anything whatever to do with statutes enacted previously to 1858. Mr. Muir Mackenzie will advise the Council before next session upon this matter, which may at any moment become one of considerable importance.

On Wednesday, also, there were presented the report of the proceedings of the whole Council in committee on the regulations for diplomas in Public Health; reports by the Education Committee on the steps taken for raising the standard of preliminary education and on certain applications from America for the recognition of an Arts course; a report by the Medical Aid Association Committee; and a report by the Special Finance Committee. The gist of these reports will be published in The Lancet next week.

A quiet and business-like session was brought to a close on Wednesday evening with a cordial vote of thanks to the President.

Thursday, Nov. 29th.

The Council met to-day with a full attendance of its members, Sir **William Turner**, the President, being in the chair.

Birmingham Consultative Medical and Surgical Institution: The Case of Dr. Henry Ward Irvine.

The entire sitting was occupied with the consideration of the case of Dr. Henry Ward Irvine, registered as M.B., Bac. Surg. 1895, M.D. 1897, Univ. Dubl. Dr. Irvine had been summoned to answer the following charge as formulated by the Council's solicitor, namely:—

> That he accepted the office of consulting physician to the Consultative Medical and Surgical Institution, Birmingham, at a salary, and approved or acquiesced in the extensive advertisements issued by that institution by posters exhibited in the various manufactories, trading establishments, and mercantile offices of the city, by advertisements in the daily press, and by lithographed letters and printed pamphlets, widely circulated, setting forth conspicuously his name and medical qualifications, and referring to his special ability as a general consulting practitioner, and soliciting and inviting the public to consult him at a reduced fee. The complainant is Robert Saundby, of 140B, Great Charles-street, Birmingham, registered as Lic R Coll. Phys. Edin, 1874, M B, Mast Surg. 1874, Univ. Edin., Mem. R. Coll Surg. Eng. 1874 The Medical Defence Union have intimated that they are instructed to take up and conduct the case on behalf of the complainant.

Dr. **Irvine** attended with Mr. **Freeman**, Q.C., to conduct his case and Dr. Bateman represented the Medical Defence Union.

Mr. **Winterbotham**, the new solicitor to the Council, read the notice which had been given to Dr. Irvine.

Dr. **Bateman** said that the case was a most important one, as upon the decision would depend the question whether systematic advertising and touting for patients in the case of so-called charitable institutions would or would not be authorised by the highest authority of the medical profession. On the one side they had Dr. Irvine and certain leading business men in Birmingham and on the other Dr. Saundby representing the staffs of the Queen's and General Hospitals and the medical profession generally in the city of Birmingham. In the medical profession there was objection to advertising as there was in the legal profession and on the Stock Exchange, and in May, 1899, the General Medical Council passed unanimously this resolution, viz.:—

> That the Council strongly disapproves of medical practitioners associating themselves with medical aid associations which systematically practise canvassing and advertising for the purpose of procuring patients.

He admitted that this resolution was directed against a particular class of medical aid associations, but he would submit that the Consultative Medical and Surgical Institution of Birmingham came under the description of a medical aid association, although the fees charged were higher than those of the ordinary grade of medical aid associations. In 1898 Mr. Arthur Chamberlain intimated to the Hospital Saturday Fund Committee of Birmingham that he had devised a scheme for the establishment of this new institution and he invited the opinion of the committee upon it. His proposals were that an institution should be established with a small governing body, that suitable rooms should be taken in the centre of the city, that a properly qualified consulting physician and a properly qualified consulting surgeon should be employed with a salary each commencing at £500 a year, and that there should be a uniform fee of half a guinea, the fee going to the institution. This scheme was adopted. Dr. Irvine had been employed as consulting physician and the institution had been set in operation. The subject was discussed at a meeting of consultants in Birmingham and a conference took place between representatives of the medical profession and the Lord Mayor and others. The consultants offered to accept a fee of half a guinea in all cases where the patient was unable to pay the usual fee. In this way they were prepared to meet the alleged want in the city, but this offer was not accepted and the negotiations came to nothing. In the month of November advertisements were published in the lay papers which he frankly admitted did not contain the name of Dr. Irvine. A pamphlet was circulated in the manufactories, trading establishments, and mercantile offices in the city. Of this pamphlet and other advertisements he presented copies to the Council. He also presented a copy of a card on which the following was printed: "The Consultative Medical and Surgical Institution, Birmingham. Objects: To lessen the strain upon hospital charity by providing on terms within and under conditions suitable to their pecuniary means and position medical and surgical aid to those who would otherwise seek it gratuitously or be unduly taxed by paying the usual consultative fees." He further presented two depositions to the effect that this card was exhibited in the dining-room and bar of a restaurant and in a hairdresser's shop. It would probably be argued that this institution was carried on on the same lines as a hospital, but such was far from being the case. There was no hospital consulting physician or surgeon who received a salary or for whose services a fee was charged. This institution was in course of being registered under the Companies' Act as a company carried on not for profit. It was regarded by its originators not as a charity but as a place where a man could claim medical aid as of right and it was conducted on purely business principles. Had Dr. Irvine, apart from this institution, allowed his name, address, qualifications, hours of consultation, and fees to be advertised by these bills, posters, pamphlets, and newspaper paragraphs there could have been no question about his conduct being "infamous conduct in a professional respect," and the fact that this advertising was done under the ægis of this institution managed by laymen did not, in his opinion, alter the gravity of the professional offence and could not be held to excuse or to palliate such conduct.

Mr. FREEMAN, opening the case for Dr. Irvine, took exception to the two depositions handed in by Dr. Bateman on the ground that his client had received no notice of them and therefore had had no opportunity of bringing rebutting evidence.

Mr. MUIR MACKENZIE, legal adviser of the Council, said there was practically nothing new in them.

Mr. FREEMAN pointed out that the depositions said that the cards were seen in particular premises, indicating that there had been systematic advertising, which he entirely denied. Unless the documents were withdrawn he would apply for an adjournment of the case.

After conferring in private for a time the Council decided not to receive the depositions.

Mr. FREEMAN, continuing his speech, said that this institution had been set on foot by public-spirited citizens with no view whatever to their own profit. It was a philanthropic institution between which and a medical aid association there was the widest possible distinction. It was a development of the work of the Hospital Saturday Fund just as the convalescent homes at Llandudno were a development of that work. The feeling had grown up that there was a gap in Birmingham between the hospitals and the consulting physicians and this institution was designed to fill the gap. There had been many people who went to the hospitals and obtained free medical aid who ought not to have done so, being able to pay. That was the state of things on the one hand, while on the other the fees charged by the ordinary consultants were too high for many of these people. The founder of the institution, Mr. Arthur Chamberlain, would be called and would say that was purely and absolutely a philanthropic institution and that there was no thought of its putting money into the pockets of anybody connected with it. The funds for it, indeed, had had to be provided by private charity. Unfortunately, the committee had not been able to carry with them the bulk of the medical profession. It might be that the institution was considered an invasion of the domain of the medical profession. The thing certainly was a novelty and they knew that there were professions which did not always like novelties. But the charge which the Council had to consider was a charge not against the institution but against Dr. Irvine. When the scheme had been matured the committee advertised for a consulting physician. They received applications from medical men in all parts of the United Kingdom and after due consideration Dr. Irvine was engaged at a salary of £500 a year. As for the so-called advertising, all that was done was to announce to the customers of the Hospital Saturday Fund, the working men who subscribed to that fund, that the institution was ready to commence operations. The committee sent out these cards and pamphlets to the various firms by whom the workmen were employed who had previously subscribed to the fund. This was not advertising, and indeed it was only what was done when an ordinary hospital was opened: people received notice that the boon was at their command. It was quite conceivable that these documents found their way into places where it was not intended they should be, but no blame for that could attach either to Dr. Irvine or the committee. If what had been done here were regarded as advertising the Council would be opening a very wide door indeed. Every hydropathic in the country would be an offender, for every hydropathic announced that it had a resident physician and gave his name, and many hospitals advertised the names of their staff So far from this institution being a source of profit he might say that for every half-guinea earned 30*s.* had been expended.

Mr. WILLIAM COOK, alderman of the city of Birmingham and chairman of the committee of the Hospital Saturday Fund, was then examined by Mr. Freeman and in the course of his evidence he gave an account of the work of the fund. Mr. Chamberlain's scheme, he said, was unanimously adopted by the large meeting to which it was submitted, and when the scheme had been worked out, notices with regard to it were sent out to the subscribers to the fund in the usual way. Owners of factories and workshops were, as usual, requested to post the notices in their premises. Dr. Irvine was not consulted as to the issue of the notices. There was no thought of any one being pecuniarily benefited by the institution and up to the present time the committee had lost money by it.

In cross-examinaton by Dr. BATEMAN witness said that he did not, and could not, regard the notices as advertisements, they were simply announcements. No doubt the more patients they had the less money would require to be subscribed. If Dr. Irvine was found to be worth more than £500 a year and they had the funds to pay it he supposed the committee would like to see him properly paid. His hope was that in time the institution would become self-supporting.

By Sir WILLIAM THOMSON: As the institution developed, and he believed it would develop, they might appoint not only a consulting surgeon but also another consulting physician.

By Sir JOHN BATTY TUKE: Their idea was that when they could afford it they would have other specialists at the institution.

By Mr. HORSLEY: Part of the money for the institution was being obtained from the Hospital Saturday Fund. If the institution became self-supporting it would still be part of a philanthropic institution—namely, the Hospital Saturday Fund.

Mr. W. S. ASTON, honorary secretary of the Hospital Saturday Fund and of the institution, was next examined. He characterised the notices sent out as announcements pure and simple

By the PRESIDENT: Persons of the class contemplated in the scheme of the institution were admitted to its benefits though they might not be subscribers to the Hospital Saturday Fund, but these benefits were designed primarily for subscribers.

Cross examined by Dr. BATEMAN witness said that it was quite well known in Birmingham what class of people were intended to make use of the institution. The practice was for Dr. Irvine to take the individual fees and account for them collectively to him.

By Sir CHRISTOPHER NIXON: The committee had seen the register kept by Dr. Irvine and they were convinced that there had been no abuse of the institution.

By Dr. WINDLE: Over 2000 cards were sent out to the firms whose workpeople subscribed to the Hospital Saturday Fund. There were hairdressers and restaurant keepers who subscribed, and they, like the rest, would receive cards. Though there had been no withdrawing of the notices they had not felt that there was any need to repeat the issue of them; the notices, indeed, had served their purpose.

Mr. ARTHUR CHAMBERLAIN, Justice of the Peace, Birmingham, was next examined. In answer to Mr. FREEMAN he said that the question had been asked, Was this Consultative Medical and Surgical Institution of Birmingham a charity? He wished to say that it was a philanthropic institution which at the present moment was not self-supporting but which the managers of it hoped to see become self-supporting. He certainly should not like it called a charity because one of the objects the management had in view was the preservation of the self-respect of persons who ought not to seek aid from a hospital, but were yet in need of some higher advice than they could get from their street doctor. It was ridiculous to suggest that the gentlemen who had founded the institution were in any way pecuniarily interested in it or had any thought of making money out of it. He himself had subscribed £200 to the fund. They wished to have a medical man who could be consulted in preference to the ordinary or general practitioner who had to attend workmen, school teachers, and others, and the managers had found that the class of people who came to consult Dr. Irvine were of the class for whom the institution was originated. Everyone of them belonged to the class of persons who would have sought gratuitous advice or ought to have sought gratuitous advice, they being unable to pay the usual fee of consulting physicians. Birmingham people were not mean and they would not go to an institution like this in question to save something on the fee if they were really able to pay, and the tendency that the institution would create would be that of causing patients to go to the men who charged the higher fee, because they believed that after all they would get from these men the best value for their money. The managers of the institution believed they were creating a class of persons who would follow Dr. Irvine into private practice or go to some other consulting physician if it was inconvenient to consult Dr. Irvine in private practice. There was no hostility whatever to the medical profession of Birmingham, and he thought that the profession would agree with the managers that something of the kind of this institution was needed for the people of the town. It had been suggested that the objects of the institution were non-medical. That suggestion simply represented the state of prejudice into which certain objectors had worked themselves. Any profits obtained would be applied to the development of the institution. Any notices which had been sent out were only of the kind sent out by similar institutions. What had been put into the newspapers was a notice which he should call an advertisement. From that, however, the name of the doctor had been omitted, and he was quite sure that if a general hospital was established in Birmingham the directors would publish an advertisement in much the same terms as the notice sent out by the managers of this institution. Asked if it was not intended to send out notices the witness replied that it was not intended to advertise.

Replying to the PRESIDENT, Mr. CHAMBERLAIN said that the institution had no printed regulations beyond those which were already before the Council and which set forth the rules, aims, and objects of the institution.

In cross-examination by Dr. BATEMAN the witness declared that he did not think the managers would send out notices in the event of a consulting surgeon being appointed for the institution.

Then it would be harder on him than on the consulting physician?—You are making fun now.

What difference do you make between Dr. Irvine and a "street doctor?"—I would say that it consisted in his being an M.D. Having that degree he is properly a doctor.

He is not a member of any college of physicians?—I think he holds the right to that title, but you had better ask him.

In view of endeavours being made to prejudice the public against Dr. Irvine witness thought the managers were right in telling the public what qualifications their doctor possessed.

By Mr. HORSLEY: The women's hospital in Birmingham was not a business concern but a charity. Dr. Irvine had not had surgical cases brought before him.

Then the institution is only for medical cases?—The work of the institution is restricted.

In examination by Dr. GLOVER witness said he was quite satisfied that they were not misleading the public by their announcements in respect to the institution. The patients, whether men or women, could take care of themselves. They might come once to Dr. Irvine, but witness thought they would not come twice The whole reason for the existence of the institution was the preservation of the self-respect of the patients. If the Council told him that in anything which had been done the managers of the institution had gone against the principles of the profession they could reconsider their position. But they did not consider that they had done that. Representing the managers, he came before the Council to say what they thought right and what they thought wrong.

Dr. HENRY WARD IRVINE, the practitioner complained of, was thereupon called. In answer to Mr. Freeman he said that he had satisfied himself that the Birmingham Consultative Medical and Surgical Institution was a philanthropic institution, the promoters of which received from it no gain whatever. He had taken special pains to make sure that that was so. He was not consulted in any way about the advertisements, but he believed that in one of the advertisements his name did not appear at all. He had never seen the posters anywhere.

Was there anything in the nature of general or systematic advertising?—Certainly not. Nothing was done more than was usual at the opening of such institutions. In Dublin they had a similar procedure to that followed in Birmingham and there there were placards issued which contained the names of the doctors and staff.

So far as you are aware have you lent yourself to systematic advertising?—Certainly not.

Until you received notice from the Council had you any idea that you were doing anything wrong?—Certainly not.

In answer to further questions witness mentioned that after receiving the notice from the Registrar of the Council he had consulted with practitioners in Birmingham who had told him they thought he would hear nothing more about the matter. There was no rule about dealing with any special class of people, but so far as he was aware those who came to him were of the class of people to whom Mr. Chamberlain referred. All cases he had to do with were entered by him in the "Case-book." He was referred to as "consulting physician," but the phrase was not his. However, it denoted nothing.

Dr. BATEMAN asked to see the agreement which Dr. Irvine had with the managers of the institution.

Mr. FREEMAN showed him a copy of it.

Dr. BATEMAN wanted to know if Dr. Irvine had read the annual report of the institution.

The WITNESS replied that he did not know that he had.

Dr. BATEMAN reminded Dr. Irvine that it was said that a large number of advertisements had appeared. Had it never struck witness to inquire whether his name was connected with these advertisements, or might the Council take it that Dr. Irvine, as he had said, had never seen one of the objectionable placards?

The WITNESS: I never saw one.

Dr. BATEMAN: Is there not one in the institute?

The WITNESS: Oh, yes.

You consider that there is nothing in the title of consulting physician?—Nothing.

Do you deal with both surgical and medical cases?—With medical. I have refused surgical cases. I have no record of the number I have refused. Perhaps they would amount to a dozen.

Mr. FREEMAN, at this stage of the inquiry, informed the Council that the agreement with Dr. Irvine showed that it was made on Feb. 28th, 1900. It employed Dr. Irvine for one year certain and he was not to carry on any separate practice.

Dr. BATEMAN: And he is bound over not to practise in the neighbourhood.

Mr. FREEMAN: He is to devote the whole of his time and attention to the duties of his office.

Dr. BATEMAN: Did you see people at their own homes?

The WITNESS: Yes, some.

Dr. BATEMAN: You give your services entirely to the institute and you are not permitted to practise outside; do you think that that is consistent with the etiquette of the profession?

The WITNESS: I do think so.

Replying to Mr. HORSLEY, who asked if the persons who came before him were what they represented themselves to be, the WITNESS said: Well, of course, my answer is that I ask their names and occupations.

Then the institution is precisely in the same position as many of our charities?—It is much the same as the hospitals in Birmingham.

By Sir DYCE DUCKWORTH: Sometimes the persons had a letter—a hospital letter. He wrote prescriptions which those who came to consult took away. Persons who came to consult him in some cases visited two or three times. Each visit paid to him was a consultative visit.

How does that practice differ from the practice of an ordinary medical man?—I think all medical men have to see patients alone.

Dr. GLOVER: Do you get half a guinea for each time the people come?

The WITNESS: Unless the people are destitute.

By the PRESIDENT: A patient pays half a guinea whether he is seen at his own home or at the hospital.

Dr. WINDLE: Have you suggested to the secretary at any time that the cards with your name on them should be withdrawn?

The WITNESS: No, I have not.

Mr. MUIR MACKENZIE said that he saw that in the report the consulting fees given amounted to £116. That worked out to 222 persons at half a guinea each. Did that mean that Dr. Irvine saw 222 persons?

The WITNESS: No; some names are repeated—some names appear several times. There are not 222 different names.

Then it ought to be 222 consultations?—That would be more accurate.

The PRESIDENT: You can now retire, Dr. Irvine. Do you think it necessary, Dr. Bateman, to make any reply?

Dr. BATEMAN: Certainly not.

The PRESIDENT: Then the case is closed and parties will withdraw.

The Council deliberated in private. On parties being recalled,

The PRESIDENT, addressing Dr. Irvine, said: The Council have given consideration to your case and I have to tell you that they consider the charge you were required to answer has been proved, but that the further consideration of your case has been adjourned until the session in May next. You will then get notice to appear; due notice will be given to you. But the Council regard the conduct complained of as being of a serious character and in adjourning your case they give you an opportunity to reconsider your position. That is the deliverance of the Council.

Dr. IRVINE: Thank you, sir.

The Council adjourned.

FRIDAY, NOV. 30TH.

The Council resumed its session to-day, Sir WILLIAM TURNER being in the chair.

The Case of Dr. William Allen.

The Council at once proceeded to the consideration of the case of William Allen, of Shotley Bridge, co. Durham, registered as M.D., Mast. Surg. 1877, Q. Univ. Irel., who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> That, being a registered medical practitioner, he on two occasions gave and signed certificates of death of persons on whom he had not only not attended professionally, but who had been to his knowledge attended and medically treated by an unqualified person named Burke, who was, to his knowledge, attending and treating patients and otherwise acting as though he had been a duly qualified medical practitioner.
>
> The names of the persons whose deaths were so certified are Emma Jane McCue and Hannah Margaret Longstaff.

Mr. Atherley Jones, Q.C., M.P., appeared on behalf of Dr. Allen.

Mr. WINTERBOTHAM, solicitor of the Council, explained that in this case there was no complainant before the Council and it therefore became his duty to state shortly the facts of the case and to call the attention of the Council to the documents which were in evidence. The attention of the Council was called to the matter by the fact that there was an inquiry held by a Local Government Board inspector on June 4th last into certain charges which had been made against Dr. Allen as medical officer of health. This inquiry was very fully reported and the charges then made against Dr. Allen were stated in the documents before the Council. At the inquiry evidence was given with regard to the certificates of death mentioned in the charge and the attention of the Council had been called to this evidence. The first and important question was whether Mr. Burke, who was undoubtedly and admittedly an unqualified man, was really covered or employed by Dr. Allen. At the inquiry Dr. Allen stated that Mr. Burke was in effect Dr. Renton's assistant and that therefore he (Dr. Allen) was in no way responsible for him. There was an agreement between Dr Renton and Dr. Allen that the latter was to have the entire management and to pay all the expenses of the practice and that after making certain allowances he was to receive three-fourths of the net profits of the practice. In such circumstances he hardly saw how Dr. Allen could put upon Dr. Renton *the responsibility for the* employment of Mr. Burke. With regard to the case of Emma Jane McCue there was the evidence of the husband to the effect that his wife had been attended by Mr. Burke and that Dr. Allen filled up the cause of death. In the case of Hannah Margaret Longstaff there was the evidence of the husband that Dr. Allen had never been in his house and had never seen his wife.

Mr. ATHERLEY JONES, opening the case for Dr. Allen, said that while the newspaper report from which the *précis* before the Council had been made was fairly accurate on the whole, yet it was not complete and therefore he felt under the necessity to give some account of the history of Dr. Allen's connexion with this practice. Dr. Allen was educated at the Royal University of Ireland and graduated there with first-class honours. He obtained the gold medal in 1877 and shortly after that he was appointed senior demonstrator by Professor Clelland of Glasgow, an appointment which he held for about six years and resigned owing to ill health. Thereafter Dr. Allen went as assistant to Dr. Renton at Leadgate. At that time (1884) Dr. Renton had five assistants—one each at Leadgate, Consett, Shotley Bridge, Blackhill, and Allandale; and from 1884 down to the year 1893 Dr. Allen's duties were confined to Leadgate. In the latter year a fresh arrangement was entered into whereby Dr. Allen was to reside at Shotley Bridge and take over the practice there, and was not to act elsewhere unless when specially called upon by Dr. Renton. In 1896 Dr. Renton required an assistant at Allandale. Mr. Burke was at that time studying medicine in America. Mr. Burke was married to one of Dr. Allen's sisters and at the instance of Dr. Allen's sister Dr. Renton agreed to appoint Mr. Burke to Allandale as an unqualified assistant. From 1896 until November, 1898, Mr. Burke was the unqualified assistant of Dr Renton and subject to dismissal by him. In November, 1898, a change took place because Dr. Renton, who had been in ill health for a time, determined to retire from practice. He then invited Dr. Allen to take the control of the practice with a view of purchasing it. He accepted this invitation and went to reside at Dr. Renton's house at Blackhill. The other places being all filled now by qualified men there was no need for Mr. Burke, and Dr. Allen took him to act as his dispenser at Blackhill. This state of things continued from November, 1898, until March, 1899. On behalf of Dr. Allen he submitted that he was in no way responsible for Mr. Burke at the time when these certificates were given. Indeed, Dr. Allen had nothing whatever to do with Allandale, where the deaths occurred. He was sent for in these cases merely because he was the nearest medical man, and he received no payment whatever for his services. In the Longstaff case Dr. Allen had seen the patient three months before her death, and from what he saw then and the information conveyed to him by Mr. Burke he was satisfied as to the cause of death. There was no obligation upon Dr. Allen to give a certificate. He, however, went to the registrar and told him about the time which had elapsed since he saw the patient alive, and it was after doing this that he gave the certificate. In the McCue case Dr. Allen went to the case because he was called upon, and when he saw the patient he found her alive, and accordingly he gave a certificate. He was in no way responsible for Mr. Burke attending the case. In conclusion, counsel assured the Council that his client had no thought of, or wish to, defy their regulations or to do anything inconsistent with the honourable conduct of his profession. If, perhaps, he had been a little indulgent towards Mr. Burke it was in order to provide him with the means of living.

Dr. ALLEN gave evidence in his own behalf. He bore out his counsel's statement and supplemented it. He said that once or twice he had given money to Mr. Burke for Dr. Renton and receipts for the same had been sent to Dr. Renton by post. When Dr. Renton went to Africa for his health witness took possession of his residence. That was at the beginning of November, 1898, and it was in contemplation at the time that the witness should acquire the whole of Dr. Renton's practice by purchase. There was no truth in the allegation that he took possession of Dr. Renton's residence in order to secure the several public or semi-public appointments as medical officer which Dr. Renton had held. He admitted that he had taken Mr. Burke to live with him, but he denied that he looked upon Mr. Burke as an assistant of his till March, 1899. While residing at Blackhill there had been three qualified assistants in his employment. Mr. Burke had remained with him until

December, 1899. With regard to the case of Mrs. Longstaff witness stated that he had seen her professionally about three months before her death. She had heart disease at that time, but the disease was not very bad. When he visited her on being sent for on the night she died he was informed that she had been confined ten days previously and that she had gone on all right until immediately before she died when she was taken ill. When he saw her witness came to the conclusion that there had been wasting of the heart and that her death was due to that cause. He had gone to the district registrar to ask what he should do in regard to the filling-up of a certificate. The district registrar had thereupon advised him that he required a certificate which stated the cause of death, the name of the deceased, and the time of death, adding that he was bound to accept a certificate containing these particulars. Witness asked the district registrar for a certificate form and on getting one he at once filled it up, omitting, however, any mention of the time of his last visit to the deceased. It was no unusual thing for a patient to be seen long before death and for a medical man to certify the cause of the death of that patient. Witness remembered the case of a man who had died 15 months after he last saw him. That patient was suffering from heart disease, and when he died suddenly witness had written to the coroner intimating his knowledge of the man's disease, and the coroner did not hold an inquest. With regard to Mrs. McCue witness said that he had attended her on the day of her death, but only then. He was called for. The man who came for him t[illegible] him that his wife was seriously ill and asked him to see her at once. He got to McCue's place in 20 minutes, a clergyman who was visiting at witness's place having driven him there in his trap. On entering McCue's house witness had seen an oldish woman standing in the kitchen. This person pointed witness to the room in which the patient was. The patient lay on a bed and she was pale and motionless. On going up to her witness could not find any wrist pulsation, but on putting his ear to her chest he found that there were pulsations of the heart. She, however, was *in extremis*—was in such an extreme condition that witness could do nothing in the way of treatment. She was lying with her head very low and she had not been delivered at the time. She died about ten minutes after he entered the room. Her death was brought on by hæmorrhage which had set in before his arrival. Witness had satisfied himself that the woman died during his presence in the room. After her decease witness had gone to the surgery at Allandale and there partly filled in a certificate. He did not know the deceased's name or age and he had asked his sister to get information as to these and have the certificate completed. It was false to say that he kept a book of "signed certificates."

In answer to the PRESIDENT witness stated that the Local Government Board had withheld ratification of his appointment as medical officer pending the investigation of his conduct by the General Medical Council.

Mr. HORSLEY said that he wished to ask the witness three questions.

The PRESIDENT pointed out that if the case was to go further the Standing Orders that evening must be suspended so that the Council might sit beyond six o'clock.

Dr. MACALISTER moved the suspension of the Standing Orders in order to secure the completion of the examination of Dr. Allen, and also consideration of a report by the Pharmacopœia Committee.

Sir DYCE DUCKWORTH, though not opposing this motion, entered his protest against the frequency in recent sessions of the suspension of Standing Orders with the object of prolonging sittings beyond the ordinary time of rising for the day—namely, six o'clock

Standing Orders were then suspended, but only so far as to enable the Council to deal with the Pharmacopœia Committee's report, the case of Dr. Allen being adjourned till Saturday afternoon.

Addendum to the British Pharmacopœia.

The Council thereupon proceeded to receive the completed draft of the Indian and Colonial Addendum to the British Pharmacopœia, 1898, regarding which the Pharmacopœia Committee submitted the following report:—

> The Pharmacopœia Committee, having been intrusted with the duty of preparing the Indian and Colonial Addendum to the British Pharmacopœia, 1893, have now the honour to submit for the approval of the Council copies of the completed draft of the work. The scope of the work was indicated in the preface to the Pharmacopœia of 1898, when it was stated that in the contemplated Addendum "medicinal plants and other substances suggested for inclusion by Indian and Colonial authorities" would be dealt with more fully than was possible at the time. The principles which have been observed in its construction are the same as those which have already been adopted by the Council in the British Pharmacopœia, 1898. A brief statement of the object and plan of the Addendum is included in the preface which the committee have drawn up.
>
> The preparation of the work has involved a large amount of correspondence with administrative, medical, and pharmaceutical authorities in many parts of the empire; and the committee desire to record their acknowledgments of the interest shown and the assistance rendered by those who have thus coöperated with them.
>
> The committee have within the last few months held a number of special meetings for the revision and completion of successive drafts. They believe that the final proof, subject to the correction of such typographical errors, if any, as may be detected, may now be fitly adopted by the Council and approved for publication in the manner prescribed by statute. The volume is about double the size of the Additions of 1890, which was published at the price of 1*s*. The committee suggest that, in view of the expense incurred in its preparation, 3*s*. would be a suitable price for the Addendum. The power of actually fixing the price rests with the Commissioners of Her Majesty's Treasury.
>
> To the labours of the late chairman of the committee, Dr. Leech, who continued to devote time and thought to the work up to the end of his life, and of the secretary, Dr. Tirard, the committee have been much indebted. Acknowledgments are also due to Mr. W. Kirkby of Manchester, and to Mr. E. Morell Holmes, for valuable advice and assistance in reference to questions of pharmaceutical botany. Dr. Attfield, editor of the British Pharmacopœia, 1898, has also edited the Addendum which is its supplement. He has for many years applied himself to the work of adapting the Pharmacopœia to the requirements of the empire at large and his task is now successfully completed. The committee accordingly suggest that a special vote of thanks for his long-continued services should be passed by the Council.
>
> In order that the Addendum may be issued to the public before the end of the present year the committee recommend: (1) that the completed draft (subject to the correction of typographical errors, if any) be adopted by the Council as the Indian and Colonial Addendum (1900) to the British Pharmacopœia, 1893; (2) that the President and chairman of the committee be authorised to communicate with the Commissioners of the Treasury on the question of the price to be fixed for the Addendum, to arrange for its publication, and to make the proper statutory announcement thereof by notice in the *London*, *Edinburgh*, and *Dublin Gazettes* (Medical Act, 1862); (3) that pending formal publication the committee be empowered to distribute "advance copies" to the medical and pharmaceutical journals and to arrange that copies may be placed for the inspection of the public in the Council's offices in London, Edinburgh, and Dublin.
>
> The committee further recommend: (4) That the thanks of the Council be conveyed to Dr. John Attfield, F.R S , for his long-continued and valuable services as editor of the British Pharmacopœia, 1898, and of the Indian and Colonial Addendum, 1900.

Dr. MACALISTER, in submitting the foregoing report, remarked that the urgency in respect to it arose mainly from the fact that this (Friday) night was the night on which the mails went out. The addendum referred to was a supplement up to date to the new edition of the Pharmacopœia, but it had been a long time in preparation. As a matter of fact, it had been suggested so far back as 1857, and since that year the facts embodied in it had gradually been collected. A large number of experts in all divisions of the empire had given assistance in its preparation, which had been most careful. The Pharmacopœia Committee had gone over the whole work line by line, word by word, no less than three times. He (Dr. MacAlister) himself had gone over it ten times and it was impossible to say how often Dr. Attfield, the editor, had revised it, as the times he had gone over it were innumerable. The work was now one that the committee thought would be accepted by the General Medical Council. It marked a new departure as it formed the completion of the plan for a Pharmacopœia for the whole of the empire referred to in the preface of the British Pharmacopœia of 1857. It was impossible for the members of the Council to go through it and discuss it, and he hoped it would be accepted by the Council. If now accepted it was intended at once to approach the Treasury to fix the price per copy. The committee considered that that price should be 3*s*., and it was in contemplation to print as many as 10,000 copies. As to the copyright, that unfortunately extended to the United Kingdom only. He believed that it was impossible to get copyright for it in the United States of America.

Sir WILLIAM THOMSON asked if the copyright could not be extended.

Dr. MACALISTER replied that he was afraid that it could not be extended.

Mr. BROWN pointed out that if advance copies were now issued some people might prepare a synopsis of the contents.

The PRESIDENT said that the General Medical Council had got the copyright for the United Kingdom. They meant to adhere to it and they had made it known that they meant to defend it.

The first three recommendations of the committee, moved by Dr. MACALISTER and seconded by Dr. MCVAIL, were then adopted. The fourth recommendation was also adopted, Dr. MACALISTER moving and Sir DYCE DUCKWORTH seconding.

The Council adjourned.

SATURDAY, DEC. 1ST.

The Council met again to-day, Sir WILLIAM TURNER occupying the chair.

The Case of Dr. William Allen.

Consideration of this case was resumed by the Council.

In answer to Mr. HORSLEY Dr. ALLEN stated that the distance from Allandale to Shotley Bridge was about two miles. Both Mrs. McCue and Mrs. Longstaff died from heart disease. He had employed Mr. Burke since March, 1899, as an assistant in the ordinary sense of the word. There, however, was no agreement. Mr. Burke had simply come to him when witness separated from Dr. Renton. For a while Mr. Burke was under witness's close supervision, but the arrangement before March, 1899, was a temporary one. Mr. Burke had simply stopped on to fill a gap. He acted as dispenser but he might have seen patients.

Replying to Sir CHRISTOPHER NIXON Dr. ALLEN said that he had no unqualified assistants and that he strictly conformed to the regulations of the General Medical Council respecting the employment of assistants. It was his sister who had suggested the employment of Mr. Burke.

By Sir WILLIAM GAIRDNER: Mr. Burke was a medical student in New York for two years. After he began to reside at Allandale he went to the Newcastle School of Medicine.

By Dr. LITTLE: Mr. Burke told witness that his instruction had included midwifery.

By Sir DYCE DUCKWORTH: Mr. Burke was entitled to earn money for Dr. Renton's firm. If he received money from patients he would pay it over. Witness did not benefit by the money that went into the firm's account.

By Dr. GLOVER: Mr. Burke had not made any report to witness about Mrs. Longstaff during the ten days between her confinement and her death. Mr. Burke had told him that everything was known. From the history of the case witness concluded that Mrs. Longstaff's case was a very tedious one, but Mr. Burke said that on the first appearance of hæmorrhage he sent for witness. As regards the case of Mrs. McCue he thought that having been called in he was entitled to give a certificate.

By Mr. MUIR MACKENZIE: He certainly was aware of the General Medical Council's regulations about "covering," but when he got the notice from the Council in respect to unqualified assistants that notice did not affect him because he had no unqualified assistants. Any money that he received from Mr. Burke previously to witness's practising on his own account was Dr. Renton's money, and he had rendered accounts to Dr. Renton in respect of it.

By the PRESIDENT: He certainly did not derive any personal gain from Mr. Burke's attendance on cases in Dr. Renton's district. He wished to state that emphatically.

Did you participate in any way in the receipts derived from those divisions of Dr. Renton's districts over which you had no supervision?—None whatever. I received nothing except for my own district.

Do you admit that you were the junior member of Dr. Renton's firm?—Certainly not. I looked upon myself as senior assistant to Dr. Renton and any moneys I received from patients were received in Dr. Renton's name.

Mr. ATHERLEY JONES, Q.C., offered to call Dr. Allen's father-in-law who, he said, was a justice of the peace and a gentleman well known in Dr. Allen's district.

The PRESIDENT, however, intimated that there was no desire to hear him.

The case was then closed and the Council deliberated upon it in private. On the re-admission of the public

The PRESIDENT announced the decision. Addressing Dr. Allen he said: The Council has considered your case with great care and these are the conclusions which the Council has come to: that the charge that you were required to meet has been proved to the satisfaction of the Council; that the further consideration of the charge proved against you has been adjourned till the session of next May; you will receive due notice when the May session is to take place and then you will have to appear; and that the Council feels it to be its duty to express its sense of the gravity of the charge and gives you this opportunity to consider fully your position as regards the direct or indirect shelter of unqualified practitioners.

The Case of James Alexander Graydon.

The Council then resumed the consideration, adjourned from May 24th, 1900, of the conviction, proved to the satisfaction of the Council, of James Alexander Graydon, of 21, South-grove, Bow-road, London, E., registered as Lic. Fac. Phys. Surg. Glasg. 1870, who had been summoned to appear before the Council in consequence of his conviction, as shown by the following copy of the certificate:—

In the County of London and }
In the Metropolitan Police District. }

Before the Court of Summary Jurisdiction sitting at the Thames Police Court in the said County and District.

The Fifth day of March, One thousand nine hundred, James Alexander Graydon (hereinafter called the Defendant) is this day convicted for that he on the Fourth day of March, One thousand nine hundred, at South-grove, Mile End Old Town, in the County and District aforesaid, did unlawfully assault Henrietta Graydon, the Complainant in this behalf.

And it is adjudged that the defendant for his said offence do forfeit and pay to the clerk of this court the sum of 21*s*.

And in default of payment it is adjudged that the defendant be imprisoned in Her Majesty's prison at Wandsworth, and there kept to hard labour for the space of seven days, unless the said sum be sooner paid.

FREDK. MEAD,
One of the Magistrates of the Police-courts of the metropolis.

I hereby certify that the above is a true copy of a conviction kept amongst the records of the county of London.

RICHD. NICHOLSON,
May 3rd, 1900. Clerk of the Peace for the said county.

The PRESIDENT, addressing Mr. Graydon, said that in May [illegible] had been admonished as to his conduct during the interval of adjournment and told the kind of evidence as to his conduct which he would have to produce at this session.

Mr. GRAYDON presented three certificates of character and conduct—one from a medical practitioner, another from a clergyman, and the third from a gentleman connected with the Church Army. In reply to the PRESIDENT he said that he was no longer in practice but was associated with a branch of the Church Army.

After the Council had deliberated in private for a time the PRESIDENT announced to Mr. Graydon that the Council did not see fit to erase his name from the Register.

The Case of Andrew Alexander.

The Council resumed the consideration, adjourned from May 26th, 1900, of the charge proved against Andrew Alexander of Blaydon-on-Tyne, registered as Lic., R. Coll. Phys. Edin. 1885, Lic. R Coll. Surg. Edin. 1885, Lic. Fac. Phys. Surg. Glasg. 1885, who had been summoned to appear before the Council on the following charge:—

That, being a registered medical practitioner, he covered an unqualified person named Tait, whom he employed or purported to employ as an unqualified assistant and whom he permitted and enabled to attend on and administer medical relief to patients and carry on medical practice as if he were a duly qualified practitioner.

Mr. APPLEBY, solicitor, Newcastle-upon-Tyne, appeared as the legal representative of Mr. Alexander.

The PRESIDENT said that Mr. Alexander had sent to the Council letters and other documents as to his conduct since the May session.

Mr. APPLEBY said that after the proceedings in May his client at once dismissed the assistant and since then had endeavoured to carry out the requirements of the Council to the fullest extent.

Mr. ALEXANDER, in reply to questions addressed to him by members of the Council, said that he now carried on the practice without assistance and found that he was quite able to do so, the work having diminished somewhat.

The PRESIDENT, after the usual deliberation *in camerâ*, said, addressing Mr. Alexander: The Council, having considered the further evidence which you have submitted, has decided to take no further steps in your case and that the Registrar is not directed to remove your name from the Register.

Removal from the Dentists Register.

The Council next dealt with the case of William Vansittart, of 4, Westbourne-grove, Bayswater, London, W., in regard to whom the Dental Committee presented the following report:—

REPORT ON THE CASE OF WILLIAM VANSITTART.

The complaint against William Vansittart having been referred to the Dental Committee to ascertain the facts the Dental Committee beg to report as follows:—

The committee find that the following facts were established by the evidence:—

1. That William Vansittart was registered in the Dentists Register on Jan. 11th, 1892, as having been in practice before July 22nd, 1878, and that his address in the Dentists Register is 4, Westbourne-grove, Bayswater, London, W.

2. That William Vansittart was on June 12th, 1900, convicted of the following misdemeanour—namely, that being a person over the age of 16 years and having the custody, charge, or care of a child under the age of 16 years, to wit, William Vansittart, a boy of the age of 10 years, he did unlawfully and wilfully neglect the said child in a manner likely to cause him unnecessary suffering or injury to health contrary to the statute, and was thereupon ordered to be imprisoned in Her Majesty's prison at Pentonville, and there kept at hard labour for the space of three months.

The evidence before the committee consisted of a certified copy of such conviction. WM TURNER, Chairman.

The PRESIDENT informed the Council that Mr. Vansittart was summoned before the Dental Committee but did not appear.

The decision of the Council in the case was that Mr. Vansittart having been proved to have been convicted of a misdemeanour the Registrar be directed to erase his name from the Dentists Register.

The Council then adjourned.

MONDAY, DEC. 3RD.

The Council resumed this afternoon, Sir WILLIAM TURNER being in the chair.

The Case of John Martin Thomson.

Consideration was given to the case of John Martin Thomson of Clarkston, Airdrie, registered as M.B., Mast. Surg. 1891, Univ. Edin., who had been summoned to answer the following charge, as formulated by the Council's solicitor:—

> That he, being a registered medical practitioner, habitually employs as assistants for the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants, and thereby causes such persons to commit breaches of the Pharmacy Acts.

Dr. Martin Thomson appeared together with his legal representative, Mr. T. Ernest Saunt, M.R C S.Eng., barrister-at-law, instructed by Messrs. Blyth, Dutton, Hartley, and Blyth, solicitors, Gresham House, London, E.C. Mr. Peter Morison, jun., of Messrs. P. Morison and Son, S S.C., Edinburgh, appeared to represent the complainers in the case—the Pharmaceutical Society of Great Britain.

Mr. BROWN expressed the opinion that before the case was proceeded with the Council should discuss the question as to whether they had *locus standi* under the Pharmacy Acts.

Mr. MUIR MACKENZIE, legal adviser, explained that this matter had been considered and he was perfectly clear that the case came within the jurisdiction of the General Medical Council.

Mr. MORISON thereupon opened the case on its merits. He said that this complaint had been submitted on behalf of the Pharmaceutical Society because that society had felt that while they were charged with the duty of enforcing the Pharmacy Acts in Scotland a practice had arisen in that country which really nullified the statutes. Dr. Martin Thomson's case was a typical one. In it there were presented three different cases in which Dr. Martin Thomson's chemist shop had been the locus of offence—one of his assistants, named McIlwraith, having been convicted for the illegal sale of poison in 1897, and another, a man named John Thomson, who was no relation of Dr. Martin Thomson, having been convicted twice since that year for a similar offence. In the second of the three cases, one of John Thomson's, the poison—laudanum—which had been sold to a little girl named Waddell had been used by the girl's mother to commit suicide with. Looking to these convictions it could not be said that Dr. Martin Thomson was at all in ignorance of the law. His case seemed rather to be one of a person defying the law. Practice of the kind Dr. Martin Thomson was charged with had been rife in Scotland for a considerable time. There had been as many as 46 prosecutions of unqualified chemist and druggists' assistants, and the Pharmaceutical Society now took it to be their duty to bring the matter to the notice of the General Medical Council so that something might be done in order to stop the practice complained of. The present case was fully stated in private print before the Council, and he and the Pharmaceutical Society's assistant secretary, who was in attendance, would prefer that the Council should judge of the matter from the opinions reproduced in the print which had been expressed from the bench by the judges before whom the prosecutions he had referred to were proceeded with.

At the suggestion of the PRESIDENT Mr. MORISON proceeded to read an affidavit made by Mr. John Rutherford Hill, Edinburgh, assistant secretary of the Pharmaceutical Society, who attends to the business of the society in Scotland. This affidavit bore out Mr. Morison's opening statement. It declared that Mr. Hill knew of the practice complained of in this case being carried on in the large towns of Scotland. It referred to the custom prevailing in Scotland of medical practitioners owning chemist and druggist shops, with surgery attached, and pointed out that it was the custom for the medical practitioner to attend a shop for two hours or so and leave the place for the rest of the day in the entire charge of an assistant who was not qualified under the Pharmacy Acts of 1852 and 1868. The Pharmaceutical Society regarded this custom of thus employing unqualified assistants as not only constituting a serious danger to the public but as really the "covering" of unqualified persons so as to enable them to practise. The affidavit further declared that Mr. Hill had produced the evidence for the prosecution in the 46 cases referred to and stated that Mr. Hill was present and heard all that took place in regard to them. Mention was specially made of the cases of Dr. Martin Thomson's assistants and the explanation was given that the law was that the actual seller was the person who made the sale and a conviction for illegal selling could take place only in the case of an assistant who sold and not in that of his employer. In concluding Mr. Morison mentioned that the unqualified assistant, John Thomson, was still in charge of Dr. Martin Thomson's chemist shop.

Mr. HILL was called to prove the truth of his affidavit and, in answer to Sir HECTOR CAMERON, he explained that an assistant qualified under the Pharmacy Acts could sell to children without offence.

Mr. MORISON wished to go into the witness-box in order to corroborate Mr. Hill's evidence in regard to what took place in the Sheriff's Court at Airdrie, Lanarkshire, at John Thomson's two convictions, but as Mr. SAUNT stated that the defence did not dispute these two convictions the PRESIDENT pointed out that what Mr. Morison offered to do need not be done. The case in support of the summons was thereupon closed.

Dr. MARTIN THOMSON was then called in his own behalf. He stated that he was now employing a fully-qualified man in his shop at 141, Grange-road, Airdrie. Neither McIlwraith nor John Thomson had ever acted as a medical assistant to him. Both had sold poisons, but not with his consent. They were to sell only if he was present in the surgery. After his conviction McIlwraith had been dismissed. John Thomson had been kept on and was still doing duty in the shop. The reason of that was this, that witness could not get an assistant with the proper qualifications whom he might employ permanently. He had tried to get such an assistant, but there was great difficulty in Scotland in getting assistants qualified under the Pharmacy Acts. John Thomson was about 25 or 26 years of age and he was a thoroughly able man. McIlwraith was also a capable man. The qualified man he had at present was not a permanent assistant. He was with witness for a fortnight only while a wholesale druggist firm in Glasgow was trying to get him a man whom he could employ permanently.

In cross-examination Mr. MORISON asked why John Thomson was not dismissed after his first conviction. Witness replied that that was because he had given him instructions not to sell poisons while witness was not at the shop. Asked if he admitted the necessity of having a qualified assistant in the shop witness replied that he admitted the necessity there was for the sale of poisons when he was present in the surgery. He could not tell daily from the appearance of the bottles whether John Thomson was or was not selling poisons, because the sale of poisons in his shop had always been very rare, so much so that he did not think the whole sales, apart from what was used for private prescriptions, would amount to £3 a year.

You have seen that the Medical Council requires immediate personal supervision of such persons as John Thomson; do you say that the sales in regard to which your assistants were convicted were made under your personal supervision?—No; otherwise the men would not have been taken into court.

Replying to Mr. HORSLEY, Dr. MARTIN THOMSON said that his shop in Grange-street, Airdrie, was open from 9 A.M. to 7 P.M. Witness attended at it from 11 A.M for an hour and from 6 to 7 P M.

Mr. HORSLEY wished to draw attention to a statement in Dr Martin Thomson's reply to the Council's summons. The notice issued by the Council as to the employment of unqualified assistants set forth that its provisions did not apply to the legitimate employment of dressers, midwives, and dispensers. Dr. Martin Thomson, perhaps relying on memory, seemed to have read that notice as having set forth that the employment of unqualified dispensers and surgery attendants was permissible. There was a very substantial difference between these two readings, and what he wished to ask was this: whether after the first conviction witness considered the subsequent employment of John Thomson as legitimate employment?

The Witness: I thought so.

Mr. HORSLEY: Why did you think so in view of the fact which had been proved that such employment was contrary to the conditions of the Pharmacy Acts?

The Witness: Because the custom is so universal in the West of Scotland, all round about, and even in the East of Scotland, and it has been so for years.

Mr. HORSLEY: Then I am to take that as an answer to my question?

The PRESIDENT: Yes.

Sir DYCE DUCKWORTH: How many times would it happen that the sale of poison was refused because you were not in the surgery?

The Witness: That happened rarely, simply because the sale of poison was so little.

In answer to questions by Dr. BRUCE, Dr. MACALISTER, Sir WILLIAM THOMSON, Dr. LITTLE, and Dr. GLOVER, Dr. MARTIN THOMSON explained that the sale of laudanum to the girl whose mother committed suicide with the poison took place when he was absent from the surgery. He could not tell how much was asked for or what price was paid for the laudanum given out. He did not know whether it was a half ounce or not. He trusted to his assistant to keep his stock and price it so much that if he ever sold anything over the counter—and sometimes he did so—he had to ask his assistant what price had to be charged. John Thomson had been years in trade before witness got him as an assistant. Witness did not suppose that the sale to Waddell's girl was entered in the poison book. He certainly kept a poison book and certainly there were entries of sales of poisons in it. He did not know if these were all recent, but the entries were made by his assistant in his presence and he signed them. He had not brought the book with him. Prosecution of chemist and druggist assistants might have taken place in Scotland during the 12 years from 1888, but he had not noticed them or had not paid special attention to them. The prosecution of his assistant McIlwraith in 1897 was practically the first intimation that he had in regard to any objection to the employment of non-pharmaceutical assistants in chemist and druggists' shops. He had been in medical practice for about nine years, and it was years after he settled in Airdrie when he started the shop. At present there were five medical practitioners in Airdrie, the population of which was over 20,000 One of the medical men dispensed at his house, while three had shops. In addition, two pharmaceutical chemists had shops. The sale of laudanum should have been entered in the poison book.

Mr. BROWN: Under what Act?

The Witness: I do not know.

Mr. BROWN: *Don't you know that laudanum is not in the* schedule?

The Witness: I do not know

Mr. BROWN: But that is the case and laudanum may be sold openly over the counter. You said that it was common in Scotland to keep unqualified assistants in these shops. For what are they kept?

The Witness: For dispensing and the sale of drugs. It is quite common for assistants in Scotch shops to sell drugs.

Mr. BROWN: Then the practice in Scotland differs from that in England. You consider that this man, John Thomson, would be perfectly competent to use poisons in dispensing prescriptions but not to sell them across the counter?

The Witness: Yes; and if he sold over the counter it would be against my wish.

Mr. BROWN: And the fact that it was done in the Waddell case is an incident which you regret?

The Witness: Most certainly.

By Mr. MUIR MACKENZIE: He could not look up his stock of poisons, neither could he tell whether his assistant might during the hours when he was absent sell three pennyworth of laudanum. He could not tell from the stock-bottle and if there was a sale the penny or three pennies would go into the common till. No record was kept of the sale of individual articles.

By Professor YOUNG: He admitted that the bottle in which the girl Waddell got the laudanum bore the name of Dr. Martin Thomson as the seller.

Professor YOUNG pointed out that while it did so Dr. Martin Thomson was not the actual seller. That had an important bearing on another matter that was before the Council.

Mr. SAUNT addressed the Council on behalf of his client. He claimed that Dr. Martin Thomson should be entirely exonerated from blame. The Council might disapprove of the manner in which things were conducted in some parts of Scotland, but a trial such as this was not the way in which to stop the practice complained of. If the Pharmaceutical Society desired to get the law altered they had their course, but it was not correct for them to induce the General Medical Council to act as prosecutors

Mr. MORISON remarked that appeal to the General Medical Council was the only way in which his clients could get the grievance stopped, for if they took the existing law they must proceed only against the "actual sellers in fact."

After some explanations in connexion with the manner in which Dr. Martin Thomson had been summoned, which, it was declared, was thoroughly correct and adopted only after very mature deliberation, the Council deliberated on the case in private. On the public being re-admitted—

The PRESIDENT announced the decision Addressing Dr. Martin Thomson he said: The Council have very carefully considered your case and I am instructed to read to you the judgment which they have desired me to deliver to you. It is this, that the charge which you are required to meet has been proved to the satisfaction of the Council and that the further consideration of the charge proved against you has been adjourned until the May session. You will receive a notice to appear here at the May session and you will have to produce evidence on that occasion that you are no longer conducting your business in the manner in which you have been doing. The Council feel it to be their duty to express their sense of the gravity of the offence and give you this opportunity to fully consider your position. That is the judgment which has been given.

Proceedings in Camerâ.

The Council sat for the rest of the day *in camerâ.*

TUESDAY, DEC. 4TH.

The Council met again to-day, Sir WILLIAM TURNER being in the chair.

Exemptions from Examinations.

Mr. HORSLEY asked the representatives of the Conjoint Board for England whether any, and if so what, exemptions from any portion of the examinations of the Board were granted during 1897 and 1898 to candidates presenting themselves for examination by the Board.

Sir DYCE DUCKWORTH said that he understood the question referred only to the final examinations of the Board.

Mr. BRYANT said that his question was not so confined.

Sir DYCE DUCKWORTH read the following answer:—1 No exemptions were granted in 1897 and 1898 or in any other year under any circumstances from any parts of the Final Examination of the Examining Board in England. 2. Exemptions were granted in those years from the first and second examinations of the Board to students of recognised universities only. 3 No exemptions from the earlier examinations of the Board were allowed to candidates who have passed at any examinations except those of recognised universities. 4. As an example of the exemptions allowed it may be stated that candidates who had passed the intermediate M B. examination of the University of London, or the first M B. examination of the University of Oxford, or the second M B. examination of the University of Cambridge, were exempted from the first and second examinations of the Board and were admitted direct to the final examination on producing the certificates required by the regulations. This applies to Scotch and Irish universities and to certain Indian, colonial, and foreign universities recognised for the purpose. 5. It is impossible at this short notice to give exactly the number of candidates during the years 1897 and 1898 who were granted exemption from the first and second examinations, but 100 students a year would be about the number. 6 If this question has any connexion with the returns of exceptional cases sent to the General Medical Council annually it is only necessary to draw attention to the fact that the return relates to exceptional cases "in regard to length of course of professional study" and not in regard to exemptions from examination.

Mr. **HORSLEY** said that he was sorry to say that this answer did not satisfy him at all; and he would move that the representatives of the Conjoint Board in England be requested to furnish the Council in writing the individual cases of exemption from any portion of the examinations of the Board granted during 1897 and 1898. He wished, of course, to point out that he only took the case of this Board as an example.

The **PRESIDENT** suggested that the request should be addressed to the officials of the Conjoint Board and not to the representatives on this Council.

Professor **YOUNG** thought that the request should be addressed to all the examining bodies in the United Kingdom.

Sir **DYCE DUCKWORTH** agreed that it was rather invidious to single out the Royal Colleges in England in this way.

As the outcome of some further discussion the motion was passed in this form:—

That the medical authorities who grant exemptions in any part of the professional examinations which they hold be requested to furnish the Council with a detailed list of the exemptions granted by them in the examinations held during 1897, 1898, and 1899.

The Council and the Royal Colleges in England: Sharp Conflict.

The Council then resumed the debate adjourned from May 31st, 1900, on the recommendations in the report of the Education Committee on certain communications from the Royal College of Physicians of London and the Royal College of Surgeons of England. When the debate stood adjourned Dr. **MACALISTER**, seconded by Dr. **PAYNE**, had moved that the Council approve of Recommendation I., which was in these terms—viz.: "I. On the first question the committee maintain the opinion they have frequently expressed that ordinary school education should be completed before the five years' medical curriculum is entered upon; and they believe that the regulation in question is the simplest practical method of insuring this. They therefore recommend that the Council should continue to adhere to it." The regulation in question is: "That no medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council and has produced evidence that he has commenced medical study at a university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council."

The **PRESIDENT** explained that since the debate in May the opinion of Mr. Muir Mackenzie had been obtained and was now before the Council. They had also before them the opinion of Mr. Cripps, Q.C., obtained by the Royal Colleges.

Mr. **BRYANT** said that he had a great wish to make this question between the Council and the Royal Colleges as clear as possible, and with this view he had drawn up a short memorandum which he would read. The memorandum was in these terms, viz.:—

Moved by the desire to make the position of the London Royal Colleges, in the question before us, as clear as possible, I have drawn up an epitome of the reasons which have influenced them in their action, as a supplement to the full statement contained in the memorandum appended to the report of their Committee of Management, printed on page 425 of vol. xxxvii. of our Minutes for this year. The English Colleges were desirous of making chemistry, physics, and biology subjects of study before the medical student began his professional career, under the conviction that it would be desirable to have these preliminary scientific subjects studied and got rid of by an examination test before the special medical curriculum was commenced.

With this object the Colleges accepted the teaching of these subjects at such schools and institutions—other than medical schools—as in their judgment afforded a high standard of efficiency; and to test this standard the schools were visited by representatives of the Colleges, with the exception of those which had been approved by the authorities at South Kensington—and more recently most of those schools have been and all will soon have been visited.

This Council, when the Colleges made this arrangement, sanctioned their procedure, as testified by the following minute of the Council, to be found in vol. xxxi., p. 162:—

Moved by Dr. Tuke, seconded by Dr. Bruce (Dec. 4th, 1894):—

"A student who has previous to registration attended a course or courses of study in one or all of the subjects, physics, chemistry, and biology, in any university, school of medicine, or teaching institution recognised by any of the licensing bodies, may without attendance be admitted to examination in these subjects: provided always that such course or courses shall not be held to constitute any part of the five years' course of professional study."

The Colleges at that period in 1894 hoped that the students of these subjects would qualify in them before they commenced their five years' curriculum, and that the period of study of these subjects would be included in the work of the year before registration, and they did so under the opinion that the scheme as sanctioned by this Council would be a step towards the realisation of the wish that the subjects of study would soon form part of a preliminary scientific examination which the medical student would in the near future be called upon to pass before he entered upon his more special professional work.

In this hope the Colleges have been disappointed, for the sister Colleges have not shown any disposition to follow their example, and the students who adopted the scheme in London soon discovered that the six or nine months which were taken up by the study of these subjects before registration gave them no advantage over their fellow students who took these subjects up as part of their five years' curriculum, as they had still five years of professional study to fill up.

Under these circumstances the London Colleges were unable to maintain their advanced position and adopted, although with regret, the ways of the other Colleges and universities which count as part of the five years' curriculum the time spent in the acquisition of these subjects when taken either at a medical school or at a recognised teaching institution.

But in so doing the Colleges continue to recognise the teaching of the accepted schools and institutions which they had previously recognised and at the present time deduct only from the full five years' medical curriculum the six or nine months which may have been spent in the acquisition of the required information, which has, moreover, to be tested by an examination. In fact, the London Royal Colleges in this matter place themselves alongside the London University, new or old, and are satisfied—if the examination test proves satisfactory—with the teaching which preceded it. And for adopting this practice some members of this Council have expressed their strongest disapprobation of our action and assert that the London Colleges, by their change of position, have practically nullified the regulation requiring a fifth year of medical study and have reduced the curriculum to the old four years' course. Whereas, under the scheme of the Colleges as now carried out, however long a period a student might take in passing the examination in these preliminary subjects—whether it be one, two, or more years—he is still required to devote four full years to his special professional studies; whilst in following the scheme this Council is now urging us to maintain, where, as in a large number of cases, the Preliminary Science Examination is not completed in one year, the more special professional subjects are necessarily crowded into the remaining period of the curriculum, which thus becomes less than four years, and at times seriously so.

With respect to the refusal of the London Colleges to give up to this Council the approval of the list of institutions which the Colleges may recognise for the purposes of study, I can only adduce two reasons: the first being that the Colleges are authorised, if not bound, by their Charters to bear the responsibility, and consequently cannot evade it; secondly, that if we handed over to this Council the power of selection we should be imposing duties upon the Council which it could not possibly satisfactorily carry out and which do not fall within its powers.

Under these circumstances it seems a pity that this Council should have entered upon a course of action which may seem to interfere with the rights and privileges of the Royal Colleges and at the same time involve this Council in duties which they have no power to undertake.

Sir **DYCE DUCKWORTH** said that his College, the Royal College of Physicians of London, had furnished the opinion of counsel and had no further information to give. The position of the two Colleges remained as before, nothing having happened to alter it. Any change that took place must take place in this Council.

The Council agreed to receive the cases put before the two counsel and their opinions and enter them on the minutes.

The Registrar read to the Council the opinions, viz.:—

MR. CRIPPS'S OPINION.

Questions.	*Answers of Counsel.*
I. Generally, whether the General Medical Council have any and what authority to lay down rules binding the Royal Colleges as qualifying bodies, constituting the Examining Board and interfering with the exercise of their discretion in the discharge of their duties?	I. The General Medical Council have no authority to lay down rules binding the Royal Colleges, as the qualifying bodies constituting the Examining Board, nor can they interfere with the exercise of their discretion in the discharge of their duties.
II. And in particular whether the Medical Council have any or what authority to control the Royal Colleges in their selection of teaching institutions recognised by them for courses of instruction and study before admission to examination?	II. It is clear that the General Medical Council have no control or authority in the selection of teaching institutions.
III. Whether the Medical Council have any statutory or other authority for their regulations as to the registration of students and resolutions thereto (of which a print is sent herewith), or can such "regulations" and "resolutions," or any other regulations or resolutions be received by the Royal Colleges only for what they are worth as recommendations?	III. The registration of students is a voluntary Registration Council Act for the convenience of all parties concerned. The Royal Colleges can by altering their own examining regulations disregard entirely the registration of students. If the Medical Council seek to introduce qualifications for registration of students including matters quite outside their jurisdiction it may be necessary for the Royal Colleges to alter their own examining regulations; but if the Medical Council merely desire to carry out their own duties, and there is a difference of opinion between the Council and the Royal Colleges, this difference could be brought for decision before the courts.

IV. If the Medical Council have no such authority as is referred to in questions I, II, or III., then what remedy have the Royal Colleges against the Medical Council, by mandamus or otherwise, for obstructing the Colleges in the lawful discharge of their *duties by refusing registration of students?*	IV. It is not a case for mandamus, but I think an action could be brought on the Chancery side asking for a declaration that the resolution which has been communicated, and to which the Royal Colleges object, is beyond the powers of the Council, and an *infringement of the rights of the* Royal Colleges
V. Generally in the matter.	V. I should advise a meeting between representatives of the Council and the Royal Colleges in order to agree, or, in the event of agreement not being possible, to act in concert in order to obtain the opinion of the court in the least expensive and most satisfactory way.

(Signed) C. A CRIPPS.

MR MUIR MACKENZIE'S OPINION.

I have fully and carefully considered the facts stated in the case and the questions in which my opinion is desired I have also very carefully considered the effect of the provisions of the Medical Acts of 1858 and 1886 which apply to those questions, of which the most important are Sections 18, 19, 20, and 21 of the Act of 1858, and Sections 3 and 4 of the Act of 1886 I have also referred to and considered the resolutions of the General Council, the terms of which are set out at pages 74 and 161 of the Council's Minutes for 1898, which are (I assume) those, or amongst those, to which the Royal Colleges object

My opinion on the questions on which I have been asked to advise is as follows:—

1 The General Medical Council is not, in passing resolutions embodying the opinion and recommendations of the Council with regard to the course of professional study which the licensing bodies ought to prescribe for their students, and communicating those resolutions to the licensing bodies, infringing any rights of the licensing bodies, or acting in excess of the Council's powers.

2 The General Medical Council is acting within its powers and rights in prescribing a regulation to the effect that no medical student shall be registered in the Students Register until he has passed the preliminary examination as required by the Council and has produced evidence that he has commenced medical study at a university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council The contention of the Royal Colleges that by prescribing this regulation as one which must be complied with by students as a condition of being registered in the Students Register the General Council is infringing the rights of the Royal Colleges, or acting in excess of its powers, cannot, in my opinion, be maintained

3 The refusal of the General Medical Council to register in the Students Register students who do not comply with the Council's regulations as specified in the Council's resolutions will not give either to the licensing bodies to which the students belong or to the individual students any right to institute or maintain any legal proceedings against the Council.

4 *The General Medical Council has no power to compel the* licensing bodies to comply with the requirements and recommendations contained in the resolutions of the Council with reference to the courses of preliminary study to be gone through by students If the licensing bodies decline to be bound by or adopt the recommendations of the Council there is no form of proceeding by which the licensing bodies can be ordered or compelled to adopt the Council's recommendations The only power which the General Council can exercise in such a case is that of making a representation to the Privy Council. But the General Council can only make a representation to the Privy Council if it appears to the General Council, on the information which it has obtained as to the courses of study and examinations to be gone through in order to obtain the diplomas of a licensing body, by means of the inquiries which the Council can make under the 18th Section of the Medical Act of 1858, and the attendance of members of the Council at the examinations, that the course of study and examinations of the licensing body are not such as to secure the possession by the holders of its diplomas of the knowledge and skill for the efficient practice of their profession

5 I would add in reference to the opinion of Mr. Cripps, Q C, a copy of which has been sent to me that in my opinion no such legal proceedings as are indicated in paragraphs 3 and 4 of that opinion could be maintained in the high court against the General Medical Council. (Signed) M. MUIR MACKENZIE.

In order to facilitate discussion it was agreed that the Council should go into committee of the whole Council for the consideration of the recommendation.

Dr. MACALISTER said that when he moved the adoption of the recommendation in May he pointed out that they of the Education Committee were of opinion that in the present state of the law this Council had no power to compel any body to adopt their views in regard to medical education or registration by any direct action—that all they could do if they were dissatisfied was to make a representation on the subject to the Privy Council He also pointed out that in the case of the registration of students the Students Register was a creation of their own and they had entire control over it—that they could say who should be admitted to it and who should not be admitted. It appeared to him that there was nothing in the law contrary to these views entertained by the Education Committee. Mr. Cripps maintained that they had no power to compel the Royal Colleges to do anything, and Mr. Muir Mackenzie said the same thing, and both counsel said that the rules of registration were matters within the power of the Council and the Council alone. It seemed to him that if they chose to make any rule as to the registration of students the legal opinions they had received entirely supported them as to their power of doing so. The question, therefore, was not a legal one any longer, but a question of wisdom and expediency. The question was whether it was a right and *proper thing that students should or should* not have *finished* their course of education at the ordinary school before they became technically medical students He had no doubt as to the wish and intention of the Council in this matter. The Council had decided that there should be a five years' course of medical study. There were many utterances of the Council on the subject, including this one: "That the period of professional study between the date of registration as a medical student and the date of the final examination for any diploma entitling to registration shall be a period of *bonâ fide* study during not less than five years" He had before him a list of nearly all the schools recognised by the Royal Colleges in England. Six months ago he mentioned three higher grade board schools, now called higher elementary schools, supported out of the rates, intended for children of the elementary education stage. By a recent decision of the Council of the Board of Education such schools would be open for the scientific instruction of children of not more than 15 years of age—that was to say, the child must leave such a higher grade school at the end of the year in which it was 15 years of age These schools were very well fitted for teaching chemistry and physics in their elementary aspects to children of that age, and they qualified for the examinations of South Kensington and for earning grants, but would it ever have crossed anybody's mind that such a school would be regarded as a medical school? He was credibly informed that two at least of these schools advertised that they were medical schools recognised by the Royal Colleges. Where was this going to stop? There were 100 or more schools recognised for this purpose throughout the United Kingdom. Looking at the grade or class of school already admitted, it was very difficult indeed to find a precedent for the rejection of any school, whether public or private, or board or anything else. The Royal Colleges had entered upon a course to which there was no obvious end. They would have to recognise all the schools in the country because in their own interests the various schools would have to fit themselves up with appliances for teaching physics and chemistry, That he would call the *reductio ad absurdum*. These schools were never intended to be medical schools and they were never intended by this Council to be so called. The question was whether this Council should approve of the thing if they could not stop it His own feeling was that they would be doing a most disastrous thing for medical education if they approved it. They could not control but they could at least say that the Students Register, which was issued by the authority of this Council, should not contain the names of these places, which they could not honestly approve as places of medical education. That was the only method which they had of checking what they thought was apt to become an abuse. For himself he had been wondering whether it would not do for neither this Council nor the Colleges to have anything to do with these secondary schools. How would it do if they said that no student should be registered unless he had passed a recognised preliminary examination and unless he had *studied at a recognised medical school?* If they wiped out these scientific institutions this Council would be saved all question of recognition and so also would be the Colleges. This, of course, would require to be accompanied by something else. They would have to allow that when a student had passed the recognised preliminary examination in general education he might be admissible to the preliminary scientific examination right away without having necessarily entered a medical school, and then when he did enter a medical school he would register, having got that examination behind instead of in front of him.

The PRESIDENT: That would be four years.

Dr. MACALISTER said it would still mean five years. The five years contemplated by that Council were five years of medical study, and if the schools had elaborated their education so as to include elementary drilling in chemistry, physics, and biology so much the better for the pupils who had attended them. He thought that students were as much entitled to the benefit of their education in these subjects as in Latin, or Greek, or French, or German. That was the suggestion which he had to offer. It would, of course, mean asking the Education Committee to draw up detailed rules, but it seemed to him that it would solve the difficulty and avoid a conflict between recognition and approval and all trouble with regard to the inspection of these secondary schools.

Mr. TEALE suggested that there might with advantage be a conference between the Council and the Royal Colleges.

Sir CHRISTOPHER NIXON protested that the scheme sketched by Dr. MacAlister would revolutionise the five years' medical curriculum, because if it could be once shown that favour was given to large bodies like the Royal Colleges of Physicians and Surgeons of England concessions would have to be made all round. The medical profession looked to this Council to secure uniformity of action among the medical authorities of the United Kingdom, and it should not be shown them that, after all, the Council had only the power to express pious opinions.

Dr. GLOVER, who regretted that the Council had to face such difficulty at the fag end of their present session, rose to propose a motion which he hoped would bring the discussion to a close. What he wished to move was:—

> That the President of the General Medical Council and the chairman of the Education Committee, with two other members of the latter, be empowered to meet the representatives of the Colleges with a view to the amicable settlement of this question, as suggested by Mr. Cripps, Q C., in his answer V. of his opinion, and to report to the Council.

Such a resolution, he thought, would bring the present crisis to an end. They would not come to any great disaster if they let things remain as at present, and he urged that the motion should be passed until at least next session.

Mr. TEALE seconded the proposal.

Dr. BRUCE trusted that the Council would make their five years' curriculum really five years' medical study, which he believed might be secured by the adoption of such a scheme as that put forward by Dr. MacAlister. There were deficiencies in the existing arrangement that might be remedied. For instance, the teaching of chemistry should be made far more thorough. Two or three years should be given to the subject in order to let the matter set in the student's mind, but he spoke from experience when he said that a great deal of the chemistry teaching of the present day was no more than tuition to enable students to secure a pass. Then there was the fifth year. Originally that had been proposed so as to obtain a full year for clinical study, but he challenged anyone to say that a tithe of the fifth year was given up to clinical study.

Mr. POWER mentioned that they used to have chemistry and biology taught in the second year. If they were going to eliminate them there would be this difficulty—What would they put in place of chemistry?

Dr. BRUCE: Medical chemistry.

Mr. POWER considered that Dr. Bruce was drawing a distinction that would not hold water. He should like the subjects in question taught to young people and to see them brought up to the quality given in the medical schools He hoped that Dr. MacAlister's scheme did not contemplate a sixth year of study. It seemed to mean that.

The PRESIDENT pointed out that members were wandering through matters that were not before the Council. The only subject before them was Dr. Glover's motion. In answer to Mr. HORSLEY, he added that instructions to a committee could not be given until the committee was appointed.

Dr. MCVAIL suggested that a vote on the motion should be taken at once.

Sir JOHN BATTY TUKE said that as chairman of the Education Committee he had held his tongue up to that moment simply in the hope that he might get some guidance out of the difficulty the Council were in. For many months past he had given much thought to this question, but he must confess that he still felt himself absolutely unable to come to any conclusion whatever. He could not vote for Dr. Glover's proposal because it meant only another postponement of settlement of the difficulty and he did not think the old way should be trod over time and again without result. As an individual member of the Council he wished to give expression to what he believed was in the mind of nearly everyone present, and that was this, that the Council were urgently called upon to decide whether the General Medical Council was the Council of Medical Education or whether the Council of Medical Education was to be put into the hands of the two great English Royal Colleges. That, to his mind at any rate, was the whole matter. The two great Colleges laid down regulations differing from those of the General Medical Council. These regulations, if continued, must be followed in the case of the minor bodies, and therefore the Colleges became practically the arbiters of medical education in this country. There was only one way in which to meet the case, and that was to fight it to the bitter end. He would rather fight and lose than go on in the way in which the Council were going on now. There was a demand for a new Act. If there was a new Act it would simply end the Council.

Dr. PYE-SMITH urged that if the Council were to embark on a legal struggle with the Colleges it would be to them a perfectly ruinous strife. They should go to almost any point sooner than go to law. If they gave up mutual recriminations he believed that they might come to a settlement.

Sir WILLIAM GAIRDNER said that he had seen nothing to disturb his original opinion that the Royal Colleges were moving in the right direction in trying to get elementary science teaching introduced into what Irish members called grammar schools, for he thought that the whole trend of the future would be to bring elementary science teaching into the elementary schools and make the upper forms of these schools places in which the elementary ideas of science could be communicated as the first portion of medical education. No consideration would induce him to evade in any way an attempt to turn science more broadly into the so-called grammar schools. On the other hand, he thought that the Colleges, as a matter of expediency, were wrong in taking upon themselves to lop off, as it were, one of the five years of medical study as set forth in the Medical Council's scheme. Now that they had taken the step he strongly wished that something like what Dr. MacAlister had suggested could be adopted as likely to bring them out of their difficulty, and meanwhile he should support Dr. Glover's motion.

Dr. MCVAIL, on the other hand, was opposed to Dr. Glover's proposal on the ground that it meant delay for another six months at least and the Council might take it for granted that the triple board in Scotland and the double board in Ireland would before the end of the period named have made their arrangements on the lines of those of the English Colleges, so that if the Council went into conference with the Colleges now they would be losing six months that they would never recover.

Mr. BALL contended that the matter under discussion was one of vital importance to the Irish medical corporations, and his belief was that if a large body like the Conjoint Board of England insisted on continuing in the course they had adopted in respect to the preliminary medical subjects other licensing bodies would have to follow so as to be able to face the very great competitive advantage which the English Conjoint Board would have.

A division was then taken, but as only eight members voted in support and the rest against Dr. Glover's proposal was rejected.

Dr. MACALISTER, seconded by Dr. MCVAIL, moved the adoption of Recommendation I., the text of which appears above.

Dr. PAYNE agreed with the spirit of Dr. Pye-Smith's remarks and expressed the hope that nothing like legal proceedings as between the two bodies interested would be adopted. Still, it appeared to him that if legal proceedings were to be avoided some concession was needed and that concession would require not to be a one-sided concession. The difficult matter was to find something that would prove acceptable.

Mr. HORSLEY, remarking that he had not spoken on this question himself, but considered that it had been amply argued by other members of Council, moved the closure.

Dr. BENNETT seconded the motion.

On a division 21 voted for the closure and 5 against. Three members did not vote and two were absent.

Sir DYCE DUCKWORTH explained that one reason why he had voted against the closure was that he had been seeking an opportunity to speak all the afternoon and had not obtained it.

The Council proceeded to a division on the proposal to adopt Recommendation I., with the result that 21 voted for the recommendation and 5 against. Again three members did not vote, while two were absent.

The Council resumed and approved of the report of the Committee's adoption of the recommendation.

Dr. MACALISTER moved—

> That the Royal Colleges should be informed that the Council had resolved to adhere to their regulation in regard to the registration of medical students which came into effect on the 1st of January, 1900.

Sir J. BATTY TUKE seconded.

Sir DYCE DUCKWORTH advised the Council to consider the full gravity of the position they had reached in deciding to send to the Royal Colleges intimation of their adherence to their former regulation in regard to the registration of medical students. He could not say what would be the result, but his own impression was that the Council's decision could not possibly receive the assent or the agreement, at all events, of his College—the Royal College of Physicians of London. The state of tension would continue in the future as it had been going on for the last 12 months, and he supposed the ultimate result, if the Council also resolved to adopt their Recommendation III., would be that the Royal College of Physicians would open its own office for registration. He reminded the Council that the Royal Colleges in question had to maintain intact the rights and privileges which they possessed under Acts of Parliament and Royal Charters, and their officers had to yield nothing to anybody. That they meant to do, and recognising fully the state of tension which at present existed and lamenting it very much he wished to say with an impartial voice—perhaps this was one of the last times he was using it in the General Medical Council—that he did think that the Council were overstepping their boundaries and going outside the Act in order to encroach in any way on the privileges of the Royal Colleges. He did not think that members of the Council realised what would happen if the Conjoint Board of Scotland was to be treated in the way the English Royal Colleges had been treated. There were medical bodies in this country who took no precautions whatever in respect to education, but the General Medical Council for some reason did not touch them. If the two English Royal Colleges were on all fours with these bodies, how was it that the state of tension between the Colleges and the Council had arisen?

Dr. MACALISTER: The Royal Colleges are the only bodies that have raised objection.

Mr. BROWN: If there are others name them.

Sir DYCE DUCKWORTH: The Scottish Conjoint Board have acted in the same way as the English Conjoint Board.

Sir JOHN BATTY TUKE and Dr. HERON WATSON, the representatives of the Scottish Conjoint Board, declared that that was absolutely not the case.

Sir DYCE DUCKWORTH: At all events, the Scottish Board accept all the bodies who are accepted by the English Board, and I think it is out of place and beneath the dignity of a body like the General Medical Council to attempt to enforce proceedings which they have no power to enforce.

Sir WILLIAM THOMSON reminded the Council that their regulations were not formed with regard to any particular body, but for the direction and control, if they had any control, of all the licensing bodies, and the matter came before the Council because the Royal Colleges in England alone among the bodies systematically disregarded the advice and regulation of the Council. What he had prophesied had happened, for it had come out in the course of the debate that some of the schools recognised by the Colleges termed themselves medical schools and advertised themselves as medical schools. If this Council were to have any say in medical education they could not stand by and see such a thing. It was casting a slur upon the dignity of the profession to which they belonged. Something had been said about conciliation, but he would point out that the representatives of the two Colleges had voted against the proposal for a conference. That meant, what he supposed they should have to face presently, war If the Royal Colleges in England had rights to defend, so also had the bodies in Ireland and Scotland, and they were just as jealous of them as the English Colleges. It had been said that if the English Colleges were allowed to go unchallenged the other Colleges would return to the four years' curriculum and he was authorised to say that his College would certainly do so. There surely was no reason why the Irish and Scottish bodies should be placed at a disadvantage in this respect. He therefore hoped that the Council would adhere to their regulation.

Mr. BRYANT protested against the imputation that the Royal Colleges in England had reduced the curriculum from five to four years. They had done nothing of the sort. The Colleges maintained that the best thing for a man to do in his professional education was to get rid of these preliminary subjects in his first year and not allow them to intrude into the work of the subsequent years. Some members had spoken as though the Colleges had nothing but board schools on their list, but he would remind the Council that the list contained such schools as Harrow, Charterhouse, Epsom College, and the Newcastle College of Science. In these and many other schools appearing on the list the teaching was infinitely better than in many of the schools connected with hospitals.

Dr. MACALISTER: Does Mr. Bryant mean to suggest that it is not true that there are board schools on the list?

Mr. BRYANT: Not at all.

Dr. MACALISTER: Why, I have a string of them here.

Mr. BROWN urged the Council to stand by their regulation.

The motion was then put and carried by 20 votes against 5.

On the motion of Dr. MACALISTER, seconded by Dr. BENNETT, two resolutions were passed, one to the effect that it be remitted to the Executive Committee, with such advice as they might think fit to obtain, to draw up and submit to the Council for approval a list of scientific institutions study at which shall qualify for admission to the Students Register; and the other to the effect that in the meantime individual applications for students' registration which the Registrar in the absence of special instructions cannot at present accept be referred to the Students' Registration Committee as exceptional cases to be dealt with on the lines laid down by the Council.

This closed the discussion of the subject.

Examinations of the Apothecaries' Hall of Dublin.

Sir DYCE DUCKWORTH presented reports from the Examination Committee with regard to the inspection of certain of these examinations.

The motion that the reports be received and entered on the minutes was under discussion when the Council adjourned.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Lemberg:* Dr. Victor Wehr has been promoted to an Extraordinary Professorship of Surgery; Dr. Gustav Bikeles has been recognised as *privat-docent* of the Anatomy of the Nervous System.—*Moscow:* Dr. P. Uskoff has been recognised as *privat docent* of Surgery.—*Naples:* Dr. Giulio Ascoli has been recognised as *privat docent* of Medical Chemistry.—*Tubingen:* Dr. B. Honsell has been recognised as *privat-docent* of Surgery.

THE BRITISH GYNÆCOLOGICAL SOCIETY: ANNUAL DINNER.—The annual dinner of the British Gynæcological Society was held at the Café Monico on Nov. 29th, when a most enjoyable evening was spent. Dr. W. J. Smyly, the President, was in the chair. Among the guests present were the President of the British Medical Association, Sir Henry Roscoe, F.R.S. (Vice-Chancellor of the London University), Sir William Thomson, Professor C. B. Ball, Dr. Lombe Atthill (President of the Royal Academy of Medicine in Ireland), Dr. J. Watt Black, Sir James Dick, K.C.B., R.N., Sir Christopher Nixon (President of the Royal College of Physicians in Ireland), Dr. R. Milne Murray (President of the Edinburgh Obstetrical Society), and Mr. Robert Jones. The toast of "The Guests" was (in the unavoidable absence of the Director General of the Royal Navy) responded to by Sir James Dick and Sir William Thomson. The latter referred to the work done by the Irish Hospital in South Africa and to its mobility. He described the march from Bloemfontein to Pretoria with Lord Roberts, dwelling upon the endurance, discipline, self-denial, and courage of the British soldier, and warmly repudiating the imputations which had been recently uttered by Mr. Kruger with regard to the British Army. He deplored as exaggerated and unpatriotic letters which had appeared with regard to the treatment of our soldiers in the campaign. He had not seen anything himself to justify such representations. Considering the exigencies of war and its first demands everything that could be done had been done. The Palace of Justice, a splendid building in Pretoria, in which they were located, offered exceptional advantages for the care of the sick and wounded. Within four days of its being given up to them they were able to accommodate 80 wounded and their results would compare favourably with those of home hospitals. The President of the British Medical Association in proposing the toast of "The British Gynæcological Society" referred to the foundations of the great obstetrical societies of Edinburgh and London, the latter being of a comparatively recent date as compared with the former, and he dwelt on the progress which made the foundation of a gynæcological society a necessity from the rapid advance in gynæcological science apart from obstetrics. He traced the early history of the society and referred to the good work which it had done and the great advantage which it had been to the profession at large by the diffusion of knowledge in this particular branch, and in coupling the toast with the name of the President he alluded to the high position which that gentleman occupied as an obstetrician. The President suitably replied. The toast of "The Universities and Medical Corporations" was proposed by the President of the Obstetrical Society of Edinburgh. He emphasised the objects of a university for the furtherance of research, quite apart from its teaching functions, expressing a hope that the new University of London would proceed on these dual lines which would insure its ultimate success. He believed that the corporations generally did their duty conscientiously with regard to the fitness of those whom they admitted into the profession and that they had the confidence of the public. Sir Henry Roscoe, who replied for the universities, briefly sketched the outlines on which the University of London would be conducted. There would be the same liberal attitude to all, both men and women, who could take advantage of its teaching and degrees. At the same time the high standard which had been aimed at by the London University in the past would be strictly maintained. He referred to the Institute of Preventive Medicine as a great means in the advancement of medical science, so great that it was hardly appreciated to the extent that it ought to be, and to which the liberality of Lord Iveagh had so largely contributed. Sir Christopher Nixon replied for the corporations in an interesting speech. The Westminster Glee Singers contributed considerably to the success of the evening.

LITERARY INTELLIGENCE. — Messrs. W. B. Saunders and Co. announce the immediate publication of the following works:—Beck's Fractures; Bohm, Davidoff and Huber's Text-Book of Human Histology, including Microscopical Technic; Dorland's Illustrated Medical Dictionary; Friedrich and Curtis on the Nose, Throat, and Ear; Heisler's Text-book of Embryology; Jackson's Manual of Diseases of the Eye; Leroy's Essentials of Histology; Levy's Elements of Clinical Bacteriology; Nancrede's Lectures on the Principles of Surgery; Ogden's Clinical Examination of the Urine and Urinary Diagnosis; Pyle's Manual of Personal Hygiene; Salinger and Kalteyer's Modern Medicine; Scudder's Treatment of Fractures; Stoney's Surgical Technic for Nurses; and also new editions of the following works:—Anders' Text book of the Practice of Medicine; Da Costa's Modern Surgery; Garrigues' Diseases of Women; Howell's Text-book of Physiology; Hyde and Montgomery's Venereal Diseases; McFarland's Text-book upon the Pathogenic Bacteria; Senn's Pathology and Surgical Treatment; Stengel's Text-book of Pathology; Stevens' Manual of the Practice of Medicine; and Warren's Surgical Pathology and Therapeutics.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION—This association held its autumn dinner on Nov. 28th, at the Hotel Cecil, under the presidency of Inspector-General W. H. Lloyd, R.N., honorary surgeon to the Queen. The company numbered upwards of 100 members of the association and their guests. After the usual loyal toasts the health of "Our Defenders" was proposed by Dr. Stokes and responded to by General Sir William Olpherts, V C., G.C.B, a guest of the association, who spoke in a hearty and emphatic manner in praise of the healing art, while he warned his hearers against the materialistic view that sees in a patient only so much flesh and blood. Major Clifford of the 1st Royal Engineers (Volunteer) also responded. Dr. James Little proposed the guests, for whom the Rev. Sir Borradaile Savory, rector of St. Bartholomew the Great, E.O, and Mr. Alfred Perceval Graves, the author of the famous ballad "Father O'Flynn," replied. Between the speeches there were interspersed songs from Miss Lilian Moreton and Mr. J J. de Z Marshall. Previously to the dinner the autumn meeting of the association was held under the presidency of Inspector-General W. H. Lloyd, when a resolution was passed in the following words with reference to the death of a famous member of the association, the late Sir William Stokes: "That the honorary secretaries be instructed to convey to Lady Stokes an expression of the deep sympathy felt by the members of the Irish Medical Schools and Graduates Association in her recent bereavement and of the loss they had sustained through the death of one whose conspicuous talent, genius, and eloquence not only won for him the admiration of his countrymen, but secured for him a world-wide reputation, and whose distinguished services to the association entitled him to their warmest gratitude." Dr. T. Gilbart Smith, the chairman of the council, reported that a letter had been sent to Field-Marshal Lord Roberts, V.C, inviting him to honour the association with his presence at a dinner upon his return from South Africa.

MUNIFICENT BEQUEST.—The late Mr. Edward Mackeson of Hyde-park-square, London, has bequeathed £20 614 to the Surgical Aid Society which supplies gratuitously surgical instruments of all descriptions to the afflicted indigent poor.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—The Cardiff Town Hall Committee on Dec. 3rd decided to recommend the town council to grant five acres in Cathay Park, free of cost, for the new building of the University College of South Wales and Monmouthshire. The value of the site is £20,000.

UNIVERSITY OF CAMBRIDGE.—During the past year 49 candidates have presented themselves for examination in sanitary science and 35 have obtained diplomas in Public Health. The annual appointments to syndicates and boards include the following:—Dr. D. MacAlister, General Board; Dr. H. K. Anderson, State Medicine Syndicate and Medical Board; Dr. Alexander Hill, Board of Agricultural Studies.

THE FIRST ANNUAL DINNER OF THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Under the chairmanship of Sir William Dalby, the President, the first annual dinner of this society was held on Dec. 3rd in the Regent Saloon of the Café Monico. There were present as guests of the society the presidents of the leading medical societies—namely, Dr. F. W. Pavy, President of the Royal Medical and Chirurgical Society; Mr. John H. Morgan, President of the Medical Society of London; Mr. Watson Cheyne, President of the Pathological Society of London; and Sir Richard Douglas Powell, Bart., President of the Clinical Society of London. After the toast of "The Queen" Sir Thomas Smith proposed "The Otological Society of the United Kingdom" in an amusing speech, which had, however, its serious side. When he began to practise, he said, the condition of aural surgery was rudimentary; it certainly was not a science; it might have been called an art, but perhaps it would be more correct to designate it as being then a department of practice. Referring to the methods of aural treatment he instanced the case of a successful aurist who practised entirely with the assistance of wool off the sheep's back and described this somewhat unscrupulous specialist's methods in detail. The burnt onion, Sir Thomas Smith added, was then a means in vogue of treating aural disease, and it must have been extensively practised, for even now in the upper circles of society people can be heard asking an unfortunate individual with ear trouble: "Have you tried the burnt onion?" But after Toynbee made his admirable studies of the morbid anatomy of the ear the foundation of scientific otology was laid, and Sir Thomas Smith concluded by congratulating the society on its foundation, because such a society afforded the means of organisation and discipline and concerted action in the investigation of aural diseases. The toast was replied to by the President, who said that he was glad to see there the Presidents of the principal societies in London. He took it that those gentlemen had come to dine with them not as an empty compliment only, but in order to let them know that they believed that the position of aural surgery had very greatly improved. It meant that they recognised the necessity for the Otological Society and approved of their work as found in the Transactions of the Society, but he thought also that they came for something more—namely, to welcome the Otological Society in a kindly spirit as a sister society. He was proud to stand there and say that he was the first president of a society which he believed would be of very great use indeed in the surgical world. The idea was to make the society as cosmopolitan as possible and to maintain the best interests of aural surgery in the United Kingdom. Dr. A. W. Sandford of Cork proposed the toast of "The Guests," which was replied to by Sir Richard Douglas Powell, Dr. Pavy, Mr. Pridgin Teale, and Professor Young. Sir Richard Douglas

Powell thought that it was a great matter for congratulation that in a branch of science such as that of otology they should have a society founded for the concentration of its work and interests Dr. Pavy, as President of one of the oldest societies, said that so far from grudging the establishment of the Otological Society, he considered that the result of its foundation would be to effect an advancement in aural surgery. Mr. Teale and Professor Young spoke in a similar sense.

IN MEMORIAM.—A brass tablet has been placed in the parish church of Palgrave, near Diss, by the Marquis and Marchioness of Northampton, in memory of Mr J. E Simpson, L R C.P. Lond, M.R C S. Eng, who accompanied them on their visit to the Nile but who died suddenly in Cairo in March last

THE British Medical Temperance Association held a meeting on Nov. 30th in the rooms of the Medical Society of London. Professor Sims Woodhead presided, and a paper was read by Dr. Heywood Smith on Alcohol in Relation to Women. He gave reasons for believing that female intemperance was increasing owing to several causes He urged that one of the most urgently needed reforms was the abolition of shop licences. After a discussion in which, amongst others, Dr. R. Paramore, Dr. C. R. Drysdale, Mr. E. J. Donbavand, Dr. J. J. Ridge, Mr. W. McAdam Eccles, Mrs Drysdale, and the President took part, the following resolution was unanimously adopted:—

> That this meeting having had under its consideration the prevalence of intemperance amongst women and its effects upon the health of the community, expresses its conviction that the existence of shopkeepers' licences promotes female intemperance and believes it to be a matter of urgency that they should be abolished

A vote of thanks to Dr. Heywood Smith was also passed.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of this society took place at the Café Monico on Nov. 29th, and was attended by considerably over 100 members of the society and their friends. The chair was occupied by the President, Dr. W. H Lamb. Among the guests were the President of the Royal College of Physicians of London and the Presidents of the Medical Society of London, the Royal Medical and Chirurgical Society, the Pathological Society of London, the Clinical Society of London, the Obstetrical Society of London, the Hunterian Society, and the West London Medico-Chirurgical Society. The toast of the evening, "Success to the Harveian Society," was proposed by Mr. John H. Morgan, President of the Medical Society of London, and acknowledged by the Chairman Mr Edmund Owen in a humorous speech proposed "The Sister Societies and Guests," and coupled the toast with the names of Dr W S Church and Dr. F W. Pavy, who both spoke in reply. The health of the President was proposed by Mr. George Eastes, who referred to the valuable services of Dr. Lamb to the society. A most excellent programme of music and recitations was provided by Mr. Bantock Pierpoint, Mr. Whitworth Milton, and Mr Frank Braine.

NOTTINGHAM GENERAL HOSPITAL.—The 118th anniversary of this hospital was celebrated on Nov 29th, when the President, the Mayor, members of the corporation, and governors attended a church service and afterwards assembled in the grand jury room of the Shire Hall for the transaction of general business. The service collection amounted to a little over £1230. The report stated that during the half-year ending June 30th last the number of patients admitted and discharged was as follows:—Admitted: remaining in hospital, Jan. 1st, 1900, 170, accidents, 164; emergencies, 647; by recommendation, 230, total, 1211, Discharged: cured, 265; to the Cedars, 312; to convalescent homes, 10; relieved, 23; made out-patients, 250; at own wish, 30; unsuitable, 23; *in statu quo*, 22; death, 118; remaining in hospital July 1st last, 158; total, 1211 The daily average of in-patients was 170, and the total number of out patients was 4419, of which casualties numbered 997. The Jubilee Wing was practically completed, and consequent on this an addition of 55 beds had been made to the hospital The pressure on the hospital for admission had been very great during the half-year, as many as 190 cases having been waiting for beds at one time The pressure would now be able to be relieved by the extra number of beds. The board, however, wished to draw the attention of the governors to the necessity of increasing the annual income of the hospital. Unless this was done the full benefit of the great efforts made for the erection of the Jubilee Wing would not be secured.

HOSPITAL MINSTRELS—An entertainment was given by the male staff of Gore Farm Hospital, designating themselves the "Hospital Minstrels," on Thursday, Nov. 29th. The audience comprised male patients and the general staff to the number of 350. An excellent programme was gone through

INFANT FEEDING.—On the suggestion of Mr S. Noy Scott, medical officer of health, the Plympton (Devon) Rural District Council resolved, at the meeting held on Nov. 30th, that a leaflet containing simple rules for infant feeding should be distributed by the registrars at the registration of each child's birth.

WATER-SUPPLY OF WADEBRIDGE.—The new waterworks which have been constructed at Wadebridge, Cornwall, were formally opened by Mrs. Ford on Nov. 28th. Mrs. Ford has given the Urban District Council the right to a number of springs from which the water-supply is derived. The reservoir is of 220 000 gallons capacity and the whole scheme has been carried out at a cost of about £6000.

ROYAL UNITED HOSPITAL, BATH—The annual meeting of the Ladies' Working Association of the Royal United Hospital, Bath, was held on Nov 26th, under the presidency of the Bishop of Bath and Wells. The report showed that during the past year this useful society had provided 1082 articles of the value of over £200, and that consequently the funds of the hospital had not been called upon to provide any linen, blankets, or quilts for the institution.

A DINNER TO SIR GEORGE HARE PHILIPSON.—On Thursday, Nov 29th, the Southern Branch of the Durham University Medical Graduates' Association entertained Sir George Hare Philipson, the founder of the association, at a complimentary banquet at the Café Royal, Regent-street, London, W Some 60 members and their friends were present, and letters and telegrams of congratulation, expressing hearty good wishes, were received from all parts of the south of England from members whose engagements prevented their attending to convey personally their felicitations to their old teacher. Dr. F. S Palmer of East Sheen, vice president of the association presided "The Guest of the Evening" was eloquently proposed by Sir James Crichton Browne, and modestly acknowledged by Sir George Philipson The health of "The Visitors" was proposed by Dr Frederick Spicer and responded to by Sir Walter Foster, M P. Sir William Turner proposed the health of the chairman, and Sir George Hare Philipson that of the honorary secretary, Dr T Outterson Wood.

PRESENTATIONS TO MEDICAL MEN.—Mr. John J Nason, M B. Lond, M R C S Eng., on his resignation after 40 years' official connexion with the Stratford-on-Avon Hospital as an honorary medical officer, is to be presented with a testimonial in recognition of his valuable services to the institution He has consented to sit for his portrait, which is to be hung in the board room, and he will be the recipient of an illuminated address, accompanied by a piece of plate —Mr James Thomas Neech, L R C P. Edin., L F.P.S Glasg., D.P H. Vict., was presented with a dinner-gong on Nov. 7th by his patients and friends at Tyldesley on his leaving the district to take up the duties in connexion with his new appointment at Halifax as a medical officer for the borough. —Mr. Thomas Carter Mitchell, M.R C S. Eng, of Topcliffe, Thirsk, Yorks, on the occasion of his resigning his practice to his son, Mr. Talbot Carter Mitchell, L S.A., and of retiring from active professional life, has been the recipient of a testimonial from the inhabitants of Topcliffe and the surrounding district in recognition and appreciation of his long professional activity amongst them. The testimonial consisted of an illuminated address in a gilt frame, a solid silver salver, and a purse of sovereigns. On the salver was engraved the following inscription:—"Presented by the inhabitants of Topcliffe and district to Thomas Carter Mitchell, Esq, M R C S, F S.A, on his retiring from the practice so ably and faithfully carried on for forty years. November. 1900"—Dr. E Magennis of Harcourt street, Dublin, was recently the recipient of an address and presentation from the medical men resident in the Lurgan Union The presentation consisted of a Harvard chair for his consulting-room, which bore on it a silver plate with the following inscription:—"Presented to Edward Magennis, Esq., M.D., J.P., by his fellow practitioners in and around Lurgan and Portadown on the occasion of his leaving for Dublin, as a token of their good fellowship and esteem. September, 1900." The address was signed by every medical man residing in the district.—At Llanelly on Nov. 29th at a meeting of the South Wales Branch of the British Medical Association, Mr. D. A. Davies, M.B. Lond., M.R.C.S. Eng., of Swansea, was the recipient of a testimonial consisting of a tea and coffee service.

CARDIFF INFIRMARY.—An effort is being made in Cardiff to free the infirmary from its debt of over £11,000. The mayor has opened a fund for the purpose and already over £1500 have been received. The *Western Mail* newspaper also has started a "Shilling Fund," which is being well responded to.

THE "BRITISH INSTITUTE OF MENTAL SCIENCE."—Before the Torquay bench of magistrates on Nov. 26th a young woman named Arundel was charged with professing to tell fortunes by palmistry with intent to deceive. Outside the defendant's rooms were printed the letters "F.B.I.M.S.," which her solicitor explained meant "Fellow of the British Institute of Mental Science." The magistrates eventually fined the woman 10*s*. and costs.

A CASE was recently heard in the C[illegible]t of Queen's Bench before Mr. Justice Wills, in which Dr. Richard Henry Barker, a medical man practising at Hungerford, sued the executors of the late Mr. James Thring Coxe to recover £201 17*s*. 9*d*. for medical attendance and fees paid to a specialist. Dr. Barker had attended Mr. Coxe, who was a man of means, for a period of 20 years. Previously to his death Mr. Coxe had suffered from acute gout and gangrene of one foot. Dr. Barker saw him every morning, for which, he said, his fee was half a guinea, and also, by Mr. Coxe's special request, at 9 o'clock every evening, when he remained with him for between half and three quarters of an hour. He also had to drive three miles from his own house to Mr. Coxe's residence, and he charged two guineas, besides supplying medicine. The defence was that the charges were excessive and that Mr. Coxe had given Dr. Barker £100 as a present shortly before his death. Mr. Justice Wills gave a judgment for the plaintiff. With reference to the £100 he said that if it were given to diminish the plaintiff's charges it could not be looked upon as a present

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Men in the New Parliament.

THE Parliament which was opened by Royal Commission on Monday, Dec. 3rd, is not by any means remarkable for the number of medical men it contains. The number is even less than in the preceding Parliament, for while four old faces disappear, there is only a single new one by way of compensation. The newcomer is Mr. F. Rutherford Harris, a gentleman well known in connexion with South African administration and finance, who at the General Election won the seat for the Monmouth District of Boroughs. Mr. Harris is a Licentiate of the Royal College of Surgeons of Edinburgh and some 20 years ago when he was a very young man he went to South Africa to pursue his profession, which he did until other interests grew upon him. The four medical members of the last Parliament who do not appear in the present one are Sir Charles Cameron (Bridgeton Division of Glasgow), Mr. J. F. Fox (Tullamore Division of King's County), Dr. G. B. Clark who was defeated in Caithness shire by Mr. Leicester Harmsworth, and Sir George Pilkington who was defeated in the Southport Division of Lancashire by Mr. Marshall Hall, Q.C., himself the son of a distinguished physician, the late Dr. Alfred Hall of Brighton. The members of the last Parliament who reappear are Mr. Robert Ambrose, Mr. John Dillon, Dr. Farquharson, Sir Walter Foster, Sir Michael Foster, Mr. R. J. Price, Sir John Batty Tuke, Dr. M. A. MacDonnell, Dr. C. K. D. Tanner, and Sir Robert Finlay, the Attorney-General, who is an M.D. of the University of Edinburgh. With Mr. Rutherford Harris this list makes a total of 11 medical men in the new Parliament. Of the eight members who backed the Midwives Bill of last session there are six in the new Parliament—viz., Mr. Tatton Egerton, Sir William Hart-Dyke, Mr. Schwann, Mr. Heywood Johnstone, Mr. Flower, and Mr. Tennant.

Opening Proceedings.

On the opening day of the session the House of Commons devoted its short sitting to the election of a Speaker. The only nomination for this office was Mr. Gully, Q.C., who held it during the last Parliament and a portion of the Parliament preceding. His nomination was seconded by Dr. Farquharson. The second and third days of the session were mainly occupied with the swearing-in of members.

The Work of the Session.

The session is a special one, called for the single purpose of voting additional money for the conduct of the war in South Africa. It is therefore not proposed to introduce the ordinary class of Bills, but to reserve them for the normal session commencing early in the New Year. The debate on the Address will, however, afford opportunity for the discussion of prospective legislation.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ASH, T. LINNINGTON, M.R.C.S., L.R.C.P. Edin., L.S.A., J.P., has been appointed Honorary Surgeon in charge of the Winsford Cottage Hospital.

BEALE, H. R., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

BOYD, STANLEY, F.R.C.S., has been appointed Consulting Surgeon to the Paddington Green Children's Hospital, London, W.

BURD, G. VANHOUSE, M.R.C.S., L.R.C.P., L.M. Edin., has been appointed Honorary Assistant Surgeon to the Winsford Cottage Hospital.

BURFIELD, T., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been re-appointed Assistant House Surgeon to St. Thomas's Hospital.

BURGHARD, FREDERIC F., F.R.C.S., has been appointed Surgeon to In-patients to the Paddington Green Children's Hospital, London, W.

BUTTERFIELD, FRANK, M.B. Lond., has been appointed Senior House Surgeon to the Blackburn and East Lancashire Infirmary.

BUZZARD, THOS., M.D. Lond., F.R.C.P., has been appointed one of the Representatives of King's College, London, on the Senate of the University of London, vice Lord Lister, resigned.

CLARKE, H. H. R., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

CUNNINGHAM, J. F., L.R.C.P., M.R.C.S., has been re-appointed House Surgeon to St. Thomas's Hospital.

DUDGEON, L. S., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

EDWARDS, T. H., L.R.C.P., M.R.C.S., has been re-appointed Assistant House Surgeon to St. Thomas's Hospital.

HARVEY, FRANK, M.R.C.S., L.S.A. Lond., has been re-appointed Medical Officer of Health by the Padstow (Cornwall) Urban District Council.

HARWOOD, H. M., M.A., M.B., B.C. Cantab., has been re-appointed House Physician to St. Thomas's Hospital.

HAWKINS, C. L., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been re-appointed House Surgeon to St. Thomas's Hospital.

HEDLEY, E. W., M.A., M.B., B.C. Cantab., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

HOGARTH, R. G., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Children's Hospital, Nottingham.

JOHNSON, ROBERT G., M.R.C.S., L.R.C.P., has been appointed Registrar and Pathologist to the North London Consumption Hospital, Hampstead, N.W.

KINGDON, E. OWEN, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Winsford Cottage Hospital.

KINLOCH, R. B., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

LEIGH, J. DICKINSON, F.R.C.S. Edin., D.P.H., has been appointed Certifying Surgeon under the Factory Acts for the Scarborough District.

LOCKYER, CUTHBERT, M.D., B.S., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Gynæcologist, Plaistow.

MCGREGOR, ROBINA, M.B., Ch.B. Edin., has been appointed House Surgeon to the Victoria Hospital for Sick Children, Hull.

MARTIN, A. E., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been re-appointed House Surgeon to St. Thomas's Hospital.

MENNELL, Z., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

NITCH, C. A. R., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

SELOUS, C. F., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

SIDEBOTHAM, G. W., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Broughton Astley District of Leicestershire.

SIMPSON, ALEXANDER, M.A., M.D. Aberd., has been appointed Medical Superintendent of the New Lancashire County Asylum, Winwick, Newton-le-Willows.

SKERRATT, F. B., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

STABB, EWEN C., F.R.C.S., has been appointed Surgeon to Out patients to the Paddington Green Children's Hospital, London, W.

STANFORD, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Hollingbourn Union.

SWAIN, PAUL, F.R.C.S. Eng., L.S.A., has been appointed Honorary Consulting Surgeon to the Winsford Cottage Hospital.

TAKAKI, Y, L.R.C.P, M R C S, has been re-appointed House Surgeon to St. Thomas's Hospital

TAYLOR, T S, M.A., M B., B C Cantab, has been re appointed Assistant House Surgeon to St Thomas's Hospital

THOMPSON, C. H, M D, M R.C P, has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham road, London, S W

TURNER, J ANDREW, M B, C M Edin D P H Camb, has been appointed Executive Health Officer to Bombay

WILLS, B S, L.R.C.P, M R C S, has been re-appointed Assistant House Surgeon to St. Thomas's Hospital

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church street, Birmingham—Assistant House Surgeon Salary £60 per annum, with apartments and board

BLACKBURN AND EAST LANCASHIRE INFIRMARY—Junior House Surgeon Salary to commence at £60 per annum, with board, washing &c

BRIGHTON, HOVE, AND PRESTON DISPENSARY—Three House Surgeons, one for each Branch. Salary £160 per annum, with furnished apartments, coals, gas, washing and attendance Apply to Assistant Secretary, 113, Queen's road Brighton

BURY INFIRMARY—Senior House Surgeon Salary £100, with board, residence, and attendance Also Junior House Surgeon. Salary £80, with board, residence, and attendance

CENTRAL LONDON SICK ASYLUM DISTRICT—Second Assistant Medical Officer and Dispenser at the Asylum at Hendon for twelve months. Salary £75 per annum, with board and residence, subject to statutory deductions Apply to the Clerk, Office, Cleveland street Asylum Cleveland street W.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY Chesterfield—Resident House Surgeon for two years Salary £100 per annum with board, apartments, and laundry

DERBYSHIRE ROYAL INFIRMARY Derby—Resident House Surgeon for twelve months. Salary £100 per annum, with apartments and board

DEVON COUNTY ASYLUM, Exminster—Junior Assistant Medical Officer Salary £125, rising £10 annually to £155, with board, furnished apartments and washing

DONCASTER GENERAL INFIRMARY AND DISPENSARY—Assistant House Surgeon Salary £40 per annum, with board and residence

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries—Assistant Surgeon Board and lodging provided

EAST SUFFOLK AND IPSWICH HOSPITAL, Thorofare Ipswich—Two House Surgeons, unmarried Salary £80 for the senior and £70 for the second, with board, lodging, and washing

EXPLORATION EXPEDITION TO NORTHERN RHODESIA.—Medical Officer for at least two years. Salary £250 a year, with reasonable expenses. All medical and surgical equipment provided Apply to Mr L. Dampier, 30, Clement's lane, London, E C

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION, Gloucester—Assistant House Surgeon for six months Salary at the rate of £30 per annum, with board residence and washing

GLAMORGAN COUNTY ASYLUM, near Bridgend—Assistant Medical Officer, unmarried Salary £150, with board (no beer or wine) lodging, and washing

GLOUCESTER COUNTY ASYLUM—Junior Assistant Medical Officer, unmarried Salary commences at £120 per annum, rising £10 yearly to £150 with board (no stimulants) lodging, and washing

GREAT NORTHERN CENTRAL HOSPITAL, Holloway road, N—Non resident Assistant House Surgeon for six months Salary at the rate of £30 per annum, with luncheon and dinner in the hospital

GUEST HOSPITAL Dudley—Assistant House Surgeon, for six months. Salary at the rate of £40 per annum, residence, board, and washing

HARTLEPOOLS HOSPITAL, 15 Town wall, Hartlepool—House Surgeon Salary £100 per annum with board, washing, and lodging in the Institution

HOSPITAL FOR WOMEN AND CHILDREN, Leeds—Non resident House Surgeon for six months Salary at the rate of £125 per annum

HULL ROYAL INFIRMARY—House Surgeon for two years, unmarried Salary 100 guineas per annum, with board and furnished apartments. Also Junior Assistant House Surgeon for one year. Salary £40, with board and lodging

LIVERPOOL STANLEY HOSPITAL.—Honorary Assistant Physician

METROPOLITAN ASYLUMS BOARD ASYLUM FOR IMBECILES, at Caterham, Surrey—Assistant Medical Officer, unmarried Salary £150 per annum, rising conditionally to £170, with rations, lodging attendance, and washing subject to statutory deductions Forms of application obtained at the office of the Board Victoria Embankment, London, E C

METROPOLITAN BOROUGH OF STEPNEY—Medical Officer of Health Salary £750 per annum Applications to the Acting Town Clerk Town Clerk's Office Limehouse Town Hall, Commercial road, London, E

MILLER HOSPITAL and ROYAL KENT DISPENSARY, Greenwich road, S E—Junior Resident Medical Officer for six months Salary at the rate of £60 per annum, with board, attendance, and washing

NEWCASTLE UPON TYNE UNION—Assistant Medical Officer at the Workhouse, unmarried. Salary £150 per annum, with furnished apartments, rations, and washing subject to statutory deductions Applications to the Clerk to the Guardians, Union Offices, Newcastle-upon-Tyne.

NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY, Douglas, Isle of Man—Resident House Surgeon, unmarried Salary £82 per annum, with board and washing free.

NORTHAMPTON GENERAL INFIRMARY—House Surgeon, unmarried Salary £125 per annum, with furnished apartments, board, attendance, and washing

WEST KENT GENERAL HOSPITAL, Maidstone.—House Surgeon, unmarried Salary 100 guineas, rising 10 per annum to 120 guineas, with board and residence Also Assistant House Surgeon for six months Honorarium at the rate of £50 per annum, with board and residence

Births, Marriages, and Deaths.

BIRTHS

BEVEN—On Dec 4th at Balham hill, S W, the wife of Octavius Beven, M D, D P H, of a son

BURGES—On Nov 25th at Hockley hill Birmingham, the wife of F A. l'Estrange Burges M R C S L.R C P Lond, of a son

DAVIES—On Nov 30th, at Home Lodge, Great Amwell the wife of Arthur Templer Davies, M D Cantab, F R C P of a daughter

MACLEOD—On Dec 2nd at The Turret Streatham, S W, the wife of Herbert W G Macleod M D M.S Edin, D P H Camb (Surgeon-Captain late H M's Service), of a son

RUBRA.—On Nov 23rd at Cecile-park *Crouch-end, N, the wife of* Henry H Rubra, M D, M R.C S, L.R.C P, of a son

MARRIAGES

O'KINEALY—TREVOR.—On the 10th of November, at St. Paul's Cathedral, Calcutta, by the Rev Canon Luchman, Captain F O'Kinealy, I M S, eldest son of J O'Kinealy, Esq, late Judge of the High Court of Calcutta, to Helen Mabel, only daughter of Rev Geo A Trevor, of Queen's gardens, London

STEVENS—JENKINS.—On Dec 1st, at Llandaff Cathedral, by the Rev J R. Buckley, assisted by the Rev Minor Canon Price, Dr. W Mitchell Stevens, 21, St. Andrew's-crescent, Cardiff to Annie, only daughter of E Jenkins Netherwood, Llandaff

WALL—FRASER.—On Nov 12th, at the Cathedral, Cape Town Charles Percivale Bligh Wall, M B, Ch B, of Butterworth Transkei, Cape Colony, to Emily C Fraser, youngest daughter of the late A. Fraser, of Island Bank, Inverness N B

DEATHS

CARROLL.—On Nov 27th, at his residence Lower Leeson street, Dublin, Deputy Surgeon-General James Carroll, M R.C S, M B Dubl

CURRIE.—On Dec 3rd at Eastbourne-terrace, Hyde-park, W, Surgeon General George Vernon Currie, I M S, aged 72 years.

HART—On Nov 25th at Wellswood Park, Torquay, in his 67th year, Gratian Charles Barry Hart, M R C S

SUTHERLAND—On Nov 30th, at *Pietermaritzburg* Natal, Peter Cormack Sutherland, M D, F R.G S., late Surveyor-General of the Colony of Natal, aged 79

N B—A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL PROVIDENT LEAGUE.

To the Editors of THE LANCET.

SIRS,—I deem it incumbent upon me to request of your courtesy some space in your widely-read columns to enable me to bring before my professional brethren a new movement which I have taken some small part in commencing. For many years past I have felt a deep interest in the various methods proposed, or carried out, for affording provident medical aid to the working classes. Being, fortunately for myself, unconnected with any such work, I have been able to take an impersonal, and therefore independent, view of the facts connected with that work—and may I be permitted to say that those facts have so deeply impressed me that my conscience has constrained me, as I am thankful to know it has constrained others, to steadfastly determine to do all that lies in our power to find and carry out some remedy for a condition of affairs which we feel justified in considering to be deeply discreditable to our profession, gravely detrimental to thousands of medical practitioners, and too often deceptive to the provident poor?

May I briefly give some of the many reasons for that belief?

In every part of the country and to an ever-increasing extent, medical practitioners are being employed by commercial agencies, bent, as is therefore natural, on paying as little to, and getting as much in return from, their doctors as they possibly can. [illegible] therefore exploit their doctors' skill and labour; sweat them so that "Jew tailors in the East End of London do not make as much out of their victims" (THE LANCET Report "Battle of the Clubs," p. 43); overwork them even more and treat them with insult and contempt (p. 103, &c.). It is heart-breaking treatment for an educated, refined man to suffer. Is it not a disgrace to the whole profession that its members should so suffer? Must it not lower the profession in public esteem?

In the next place, when a doctor contracts to attend thousands, or even let us say hundreds, of people, knowing that his average payment per visit and medicine will not be 3*d*.—I prefer to overstate the figure—it is beyond dispute that he cannot make a bare living if he devotes much time and attention to each patient. It is a physical impossibility. It is easy to say that what is worth a guinea cannot be bought for seven farthings (THE LANCET Report "Battle of the Clubs," p. 177), and that the poor cannot expect it. But, then, is it just, is it creditable, to make a contract which cannot be faithfully fulfilled? I know of men who have tried to do their contract work faithfully but broke down in the struggle to achieve the impossible. I doubt not that scores of other men have similarly worked and similarly failed.

It is well known that efforts have been made, but that they have failed, to prevent the growth of the evils of the present system. Councils and colleges have been appealed to—in vain—in the hope that they would make restrictive enactments and thus insure that, if any practitioner resigned a club appointment the conditions of which were inequitable alike to himself and to any sick members, some neighbouring practitioner or some newly-imported—generally newly-qualified—medical man would not instantly take the post in question. This has so often happened in the past that men have openly declared that however ardently they might desire to resign all connexion with medical aid associations it might almost involve them in professional ruin to do so—so completely were they at the mercy of their commercial employers, and so cut-throat was the competition in the ranks of the profession. For reasons which possess much force the authorities appear to have expressed their inability to give any assistance. On the other hand, some local efforts have been made to combat the evil—in rare instances with temporary success, but far more often with failure.

So it has been often suggested that, in the first place, the movement for reform must be central and general, so as to afford, on the one hand, the greater assistance and, on the other, to obviate the chances of local jealousies and friction. In the second place, it has been suggested that such a national union should begin by supporting those provident organisations which already treat their medical officers fairly, and by such support exert a leverage to induce similar organisations to follow the same course. Such a plan seems to be more common-sensible and more easy of fulfilment than to start a new provident organisation under medical control; because the latter would require a very large amount of capital and would involve great business responsibilities and organisation. Accepting these two principles, the working of the various friendly societies was closely investigated, and it became apparent that one of those bodies pursued utterly different methods to most of the others; and methods which appeared to obviate every one of the objections urged against the medical aid associations. This body—the National Deposit Friendly Society—has grown from a small beginning in a little Surrey village into a powerful organisation which is rapidly spreading all over the country, the membership of which is increasing by leaps and by bounds, and which already has a quarter of a million sterling invested. This society *has no contract work*. Each member can consult any medical practitioner he or she chooses. The society has a fixed scale of medical fees and if a medical practitioner accepts this scale the society pays him promptly as soon as his attendance upon the member is concluded. If the medical practitioner does not accept the scale of charges he can arrange with the member, personally, to pay any excess over the specified amount—the society still paying its fixed quota. But it is noteworthy that, in many cases, when special circumstances have been proved the society has generously defrayed the extra fees charged by the practitioner. *No contract work; prompt payments for work actually performed.* Surely these are excellent principles. The society, moreover, has established a sliding scale of fees. Under the Friendly Societies Acts it cannot establish a wage-limit for its members; but it does something better still, because the fees paid to practitioners increase upon a graduated scale according to the amount of sick-pay benefit for which the member subscribes, and which cannot exceed £3 a week. A man receiving £3 a week would have to pay his doctor 5*s*. a visit and medicine for two days—a fee which from a working man will not be condemned as inadequate by any of your readers. A member receiving 30*s*. a week sick-pay in like manner pays 2*s*. 6*d*. per visit and medicine for two days. The society has exhibited its desire to work harmoniously with the medical profession, and from every part of the country a remarkable consensus of opinion is expressed that the methods of working and the payments of this society to medical practitioners deserve professional approval. It appears, therefore, that the National Deposit Friendly Society offers a system which might with much advantage be adopted by medical men throughout the country. It has been publicly stated that the society always welcomes the assistance of medical practitioners in starting branches of the society in districts where such do not at present exist. The society is just about to commence an insurance department for the benefit of its members, and it was suggested that if practitioners willing to attend its members on the scale of fees adopted by the society formed themselves into an organised body the society would be glad to recognise that body officially and to receive from it any complaints or suggestions which the medical officers of the society might desire to make, and which in such a case would be made direct to, and considered by, the governing body of the friendly society. By this means, harmony would be secured, friction and misunderstandings prevented. The views and complaints of any medical officer would go direct to headquarters. As an earnest of their desire for such harmonious working the society offered to give the medical organisation two representatives on its governing body and to accept from the former any recommendations for the appointment of medical referees for the insurance department.

These details having been decided upon in October I addressed a circular on the first of this month to the 1500 practitioners who have in the last year attended members of the society, proposing the formation of a Medical Provident League with certain definite objects, and calling their attention to the above decisions of the National Deposit Friendly Society with the methods of which they were all familiar. Within a fortnight I received nearly 200 applications for membership of the league and many expressions of sympathetic coöperation. I therefore called a meeting of those who had sent their subscriptions, and this was held on Friday, Nov. 23rd, at Exeter Hall. It was unanimously decided to found and carry on a Medical Provident League. A provisional committee was appointed to draw up the necessary by-laws and to summon a meeting of members next May in order to elect permanent officers and a council. The meeting honoured me by electing me as president. The meeting then adopted as the objects of the league the following programme which I had ventured to suggest:—

1. To unite medical practitioners throughout the United Kingdom for their better defence and furtherance of their professional interests.
2. To bring about better arrangements for affording provident medical aid to the working classes.
3. To support such existent provident schemes as are equitable to medical practitioners; and to oppose such schemes as are inequitable in their working or management.
4. To unite and coördinate the personal influence of medical practitioners with individual Members of Parliament, in order to direct the course of any legislation which affects the interests of the medical profession or of the public health.
5. To initiate, or support, schemes incidental to, or conducive to the furtherance of, the above objects.

There are one or two points which perhaps I ought to emphasise. The Medical Provident League will be open to all registered practitioners who desire to improve the conditions of provident medical aid in this country. It will be, of course, absolutely independent of any lay organisation, but it will earnestly advocate and support those organisations—and, to commence with, the National Deposit Friendly Society—which prove themselves willing to treat their medical officers with justice and respect. The League will endeavour to bring about reforms which are urgently needed; it will endeavour to draw practitioners together in a united effort to raise the general conditions of provident work. It appeals to the whole profession to aid it in work which must be of interest and importance to the vast majority of practitioners. The League will doubtless meet with the opposition and abuse which is the accepted reward of every effort at reform; and the cold-water criticism of the superior person who has never experienced the trials and troubles of the general practitioner and whose sympathy with those troubles is very skin deep. It may be long before the League can succeed, but it has already attracted so much help, it is designed to meet so urgent a need, it is founded upon such principles of justice and professional honour that I cannot but believe that in due time it will attain its objects and will secure the success which I venture to think those objects deserve.

I am, Sirs, yours faithfully,
J. W. J OSWALD,
President of the Medical Provident League.
Kennington road, S E., Nov. 28th, 1900.

"DOES AN ADVERTISEMENT CONSTITUTE A WARRANTY?"

To the Editors of THE LANCET.

SIRS,—Many thanks for sending your issue of present date and calling attention to your notice of our suit against Mr. H. Mott of Oxford, who purchased, by correspondence, one of our five-guinea belts, and not being able to pay the full amount proposed to pay 21*s*. down and the balance in monthly instalments of 21*s* each. He had the belt just five months, during which time he failed to take any notice of any letters or statements that we sent him until we threatened suit, when he returned the belt, which showed signs from the oxidisation of the wires that he had worn it the whole time and was no doubt benefited by it. When in the witness box the judge asked him if he doubted the genuineness of the appliance as a producer of electricity and his answer was "that he did not doubt it" Mr. Mott produced no medical certificate to show that he was ill these five months, nor did he show that he, his wife, or any friend could not have returned the belt in a shorter time, but evidently held on to it till suit was threatened and it was a question of parting with four guineas. The judge was evidently prejudiced from the beginning and determined to decide against us although we called the judge's attention to the medical testimony on p 65 in the inclosed pamphlet and to the standard medical works on p. 72. That we make no claim that our appliances will cure everything we referred the judge to p. 52, No 17, where we say distinctly the appliances must not be used in cases of fever. That our appliances are beneficial may be proven from the fact that we frequently sell to poor people on the instalment system of 5*s*. weekly, or according to their ability to pay, and that we have never had occasion to sue anyone prior to this case. It is well for us to know that we cannot receive justice in the collection of an account when suit is brought against us, and we shall have to conduct our business accordingly in the future. We may add that we invite medical men as well as electricians to call on us at any time and test our appliances to their entire satisfaction. Trusting you will insert the above in your valuable journal,

We are, Sirs, yours faithfully,
J. L PULVERMACHER AND Co., Limited
Regent-street, W., Nov. 24th, 1900 (ARTHUR LOWETH, Secretary)

PAYING PATIENTS IN HOSPITALS.

AN action was recently brought by Mr. P. J. Hayes, a surgeon of Dublin, against a gentleman farmer named M'Hugh whose leg Mr. Hayes had amputated in the Mater Misericordiæ Hospital in which the surgeon recovered a verdict and judgment for £50 The verdict and judgment have now been set aside upon appeal and entered for the defendant upon grounds which show, if it needed to be shown, that those managing public hospitals should either not admit to their wards persons capable of paying for aid rendered to them or should make it clear to the patient before admission that he will be expected to pay according to his means. It is, for those connected with the management to do this rather than the individual member of the staff who may perform the operation. Mr. Justice Murphy, in delivering the judgment of the Queen's Bench Division in the case referred to, pointed out that the defendant, who had been brought from the Roscommon County Infirmary to Dublin by his own wish, was placed in a public ward and there was no evidence while he was in the hospital that any intimation was made to him that he was a paying patient or that he was treated so that he must reasonably know that he should pay or that there was any express contract. Any evidence of admissions of liability related to statements made by the patient's relatives without his authority, whereas he was quite capable of acting for himself. In these circumstances we cannot see that the decision of the court is in any way surprising. Mr. Justice Murphy pointed out that having regard to his means the patient might be acting shabbily but that was not the question which the court had to consider. We are, all of us, accustomed to the "shabbiness" of patients well able to pay who avail themselves of free medical and surgical aid, in hospitals and out of them Mr. M'Hugh appears to have broken his thigh in a horse accident and to have been brought to Dublin by his own preference; there must, therefore, have been time and opportunity to make it clear that his treatment would not be free, whether he were satisfied with the skill of the surgeons of his own district or preferred to put himself in the hands of those of Dublin. At the same time the medical profession is not one skilled at making bargains, and public opinion is often the only tribunal to which it can appeal when its aid has been distributed gratuitously to those who in other matters would deem themselves insulted if "charitable assistance" were offered to them

THE SPECIAL TESTS FOR DRUNKENNESS

To the Editors of THE LANCET.

SIRS,—In a recent case of alleged drunkenness one of the magistrates asked a witness, "*Did the doctor in your presence apply any of the* special tests for drunkenness?" I should be glad if you could inform me what the special tests for drunkenness are

I am, Sirs, yours faithfully,
[illegible] 28th, 1900. BACCHUS

** We know of none There are certain shibboleths which, if police-court reports are to be trusted, are applied by police surgeons, such as the ability to articulate clearly the words "British constitution" or "[illegible]ary abilities" Some 25 years ago at Oxford no man was considered to be drunk at a "wine" until he attempted to light a cigar with a fork.—ED L

"MOTOR-CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—I notice that the question of the utility of the motor-car for the practitioner has again cropped up in your columns and that you devote an article to its consideration in THE LANCET of Nov. 17th, p. 1452. I find, too, that it is just about a year ago (THE LANCET, Oct 28th, p 1192, and Nov 18th, p 1402, 1899) since I addressed some letters to you on the subject A further year's experience may be of utility to some who are thinking of buying, and in some cases the second year's experience may be of more value than the first Case in point—I heard of a neighbouring practitioner who bought a motor-car He was most enthusiastic, told all his friends that it was the best thing going, and that he had saved £90 in the first six months Within a twelvemonth after he had sold that motor-car, and by the time he had paid his bills for repairs and written off the loss on the sale, I doubt whether this saving was as great as he had reckoned it At all events, I believe his friends have heard less on the subject lately To my own experience, then. Since November last my car has been laid up and not available for use pretty nearly as long as it has been in use, but this includes a long spell of last winter when I did not attempt to use it at all, in fact the minute there is a quarter of an inch of mud on the roads half the utility of the car has gone I am speaking only of a solid tyre car—I know nothing of pneumatics, and after reading the *Autocar* weekly for a year or two do not want to In fact, if there are two things I would more strongly impress upon my *confrères* than others, after a careful study of motor journals, they would be (1) have nothing to do with any car containing a pump, and (2) have nothing to do with pneumatic tyres. Further, I would say, before buying a car buy the last dozen numbers of the *Autocar* You will find therein various accounts of journeys with their incidents, mainly pump and tyre, amongst them a very interesting series of papers by the well known novelist Mrs Edward Kennard, and in the last of these an interesting snap-shot of the lady on the road with a punctured pneumatic tube in her hand. Imagine this on a round with none too much time to spare It is the sort of thing that does not matter much when you are out for a fortnight's holiday and your time is your own to spend at Little Pedlington or Slowcum in-the-Hole, as the case may be, but imagine yourself on the road, getting rather late—bang goes a tyre—and you have to get down, jack up the heavy car, get off the heavy cover of the inner tube, get out tube, repair, replace, pump up More visits to pay and consulting-room appointments made at home for afterwards! How like you the prospect? Again, it is to be borne in mind that tyres are expensive; while the motive power (petrol) of the car will work out at about 3*d*. per mile, the pneumatic tyres work out at about 2½*d*. per mile.

Only in the current number of the *Autocar*, in reference to the Southsea run noticed by you, Sirs, will be found "by the time appointed for the processional descent of Portsdown Hill and entry into Portsmouth, 80 of the 100 odd cars had arrived." There it is: 20 per cent. failed to arrive at a given place in a given time. Apply the figures to one car and to country practice and there you are. You start out on a round, all goes perfectly well for four journeys, then you have had your 80 per cent. On the fifth journey your car fails to arrive at the time you expected it to Then you get your 20 per cent. Again, I will say, read Mrs. Kennard's "Cruise of the Sir Charles." You will be able to form some estimate of the frequency and duration (one of them, I think, about five days) of stoppages—no matter at all on a holiday, but simply maddening in medical practice, and bear in mind that this is a very powerful car, probably not to be bought under £600 or £700. My bills for maintenance of car, as distinct from running it, come to about £43 for the year. To this must be added at least 10 per cent. written off value of car, another £20, and it will be seen that its economy, as compared with horse-keep, is not remarkable. The motor-car is a pleasant hobby, useful on hard and fairly level roads, very little use on muddy roads or in a hilly country; as long as it is in running order it is a great boon in very hot weather, for it is faster and saves knocking one's horses about, but whoever buys a motor-car under the idea that he is going to use it in his practice and economise by giving up horses buys trouble. In addition to maintenance, running expenses, and depreciation a considerable sum must be allowed for hire when the car is unavailable.

A word as to the buying of second-hand cars. On no account buy one second hand from *anyone* without independent expert advice. I have bought horses from dealers and motors from dealers. Horsedealers have the reputation of being able to look after their own interests, but I should class them as childlike and innocent when compared with certain motor-dealers I have met. At the risk of repeating myself—have nothing to do with pumps; have nothing to do with pneumatic tyres; have nothing to do with common German tyres—insist on Connolly's tyres on *all* wheels of a car, not on driving wheels *only*. Get the best expert advice before you buy; make sure the car will go up the hills in your neighbourhood; and on the whole, do not buy at all unless you only intend to keep it as you would a yacht or a steam-launch, for pleasure mainly—and it may be useful in business. On looking over what I have written I find I have charged nothing on account of "wages," to account of car. This must be added, some portion, at all events, of a man's time, as I fancy the practitioners must be very few who would care to do all the cleaning, lubricating, and oiling for themselves. Altogether I am disposed to advise that a £20 screw, a £20 dog-cart, and annual expenses much the same, will go further in practice than a £200 car.

I am, Sirs, yours faithfully,
Stratford-on-Avon, Nov. 19th, 1900. HARRY LUPTON.

TRAVEL IN MENTAL DISORDERS.

To the Editors of THE LANCET.

SIRS,—The treatment of mental disorders by travel, discussed by the Medico-Psychological Association and reported in THE LANCET of Dec. 1st, p. 1579, is a subject upon which a poet has spoken:—

> "Oh, never let the wretched, if a choice
> Be left him, trust the freight of his distress
> To a long voyage on the silent deep!
> For like a plague will memory break out,
> And in the blank and solitude of things
> Upon his spirit with a fever's strength
> Will conscience prey."
>
> (Wordsworth's "Excursion," Book III.)

I am, Sirs, yours faithfully,
Leek, Dec. 1st, 1900. D. A. ALEXANDER.

INSTITUTIONS FOR THE GRATUITOUS TREATMENT OF PHTHISIS BY THE OPEN-AIR METHOD.

To the Editors of THE LANCET.

SIRS,—I shall be greatly obliged if you or any of your readers can inform me if there are any institutions for the gratuitous treatment of phthisis by the open-air method existing in this country.

I am, Sirs, yours faithfully,
Nov. 27th, 1900. H. H.

"HAVE MATERNAL IMPRESSIONS ANY EFFECT ON THE FŒTUS IN UTERO?"

To the Editors of THE LANCET.

SIRS,—In connexion with the recent article on the above subject in THE LANCET of Nov. 3rd (p. 1266) the following case may be of interest. Mrs. ——, 2-para, was admitted into the Clapham Maternity Hospital on account of ante-partum hæmorrhage. The patient was seven months pregnant and had had attacks of hæmorrhage at irregular and frequent intervals since the third month. Shortly after admission the patient was delivered, the membranes rupturing at the same time, and the entire contents of the uterus being expelled with one pain. The fœtus was deformed as follows. the head and the thorax were apparently normal; the entire abdominal viscera and probably part of the heart were external to the body wall. The pelvis seemed to be normal, but the sex could not be distinguished by external examination. The legs were united by skin and soft tissues in their whole length and were strongly flexed on the child's back, the knees being turned towards the back. Both feet were in a condition of talipes calcaneus. The umbilical cord was represented by a membranous band from one and a half to two inches long, so that any movement of the fœtus must have dragged on the placenta, causing the hæmorrhage. The placenta was very soft and degenerate and was incompletely demarcated, the entire chorion being villous with only small patches of smooth membrane here and there. The heart pulsated for a short time after delivery. There was no history of deformity in the family, the patient's two former children having been well formed, though the elder died during delivery. On questioning the patient, before she knew anything of the condition of the child, the information was elicited that between the second and third months of her pregnancy and before she had had any hæmorrhage she was much impressed by seeing a dog run over in the street, the lower part of the body being completely crushed and "the legs hanging off."

I am, Sirs, yours faithfully,
J. D. GRANGER, M.B., Ch.B. Glasg.,
Resident Medical Officer, Clapham Maternity Hospital, S.W.
Nov. 30th, 1900.

◆

Joseph H.—We do not give medical advice. If our correspondent's medical man thinks the condition is one that could be relieved by surgical treatment an application for admission to a hospital might be made. Our correspondent's means, from what he tells us, would not suffice to allow him to pay for the performance of the operation by his family medical man.

M.B.—1. "The Outlines of Psychology" and "The Teacher's Note-book of Psychology," both by Professor James Sully. For further information see the Student's Number of THE LANCET, Sept. 2nd, 1899, page 627. 2. There is, we regret to say, no such school.

Mr. J. Permewan.—The subject of the purity of beer is dealt with in another column. An account of the manufacture of lager beer at Messrs Allsopp's brewery at Burton appeared in THE LANCET of Nov. 25th, 1899, p. 1462.

Lex should consult "Professional Education in the United States," published by the University of the State of New York, at Albany.

A. J. R. O.—The notes have been received and we hope to publish them.

A. A. W.—We cannot say anything definite yet.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (12th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (13th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (15th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (10th).—SOCIETY OF ARTS.—8 P.M. Prof. J. A. Fleming: Electric Oscillations and Electric Waves. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. de Havilland Hall: The Diagnosis and Treatment of Thoracic Aneurysm. (Adjourned Discussion, with special reference to Treatment by Injection.)—Mr. A. Doran: Painless Calculous Pyonephrosis without Fever, Nephrectomy, Recovery.

TUESDAY (11th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Dr. Manson: A Brief Resume of the Recent Advances in the Parasitology of Malaria.—Dr. Sambon and Dr. Low: An Account of the Experiments conducted on behalf of the Colonial Office and the London School of Tropical Medicine in the Campagna and in London.—Dr. Rees: Demonstration of the Human and Mosquito Cycles of the Malaria Parasite and of the Anatomy of the Mosquito.

WEDNESDAY (12th).—HUNTERIAN SOCIETY (London Institution, Finsbury circus).—8 P.M. Council Meeting. 8.30 P.M. Papers.

SOCIETY OF ARTS.—8 P.M. Prof. F. Clowes: The Treatment of London Sewage.

THURSDAY (13th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Clinical Evening. 8 P.M. Cases and Card Specimens. 8.30 P.M.: Mr. J. H. Fisher: Case of Congenitally Imperfect Separation of Iris from Back of Cornea.—Mr. W. T. Lister: Large Dermoid Growth of Cornea in the Eye of an ox.—Mr. G. B. James: (1) Rare Example of Persistent Pupillary Membrane; (2) Large Pigmented Area below Disc, probably of the nature of a Coloboma.—Mr. A. S. Morton: Growth on Cornea.—Mr. F. Fergus: A Case showing an Easy Operation for Ptosis.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Mrs. D. Colman, M.D. Lond.: Causes of Failure in the Health of School Girls.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Mr. F. Jordan, Mr. B. Jessett, and Dr. H. Snow. Papers:—Dr. Elder: Some Unusual and Interesting Abdominal Cases.—Dr. Hodgson: Circulatory Phenomena as a Sequela of the Pregnant Uterus.

FRIDAY (14th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Meeting.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. Tyson: A Case of Ankylostomiasis.—Dr. Calvert: A Case of Hæmatoporphyrinuria.—Dr. J. Fawcett and Mr. Steward: A Case of Pneumococcal Suppurative Pericarditis treated by Incision and Drainage.—Mr. W. G. Spencer: Bursæ filled with Concretions of Urate of Soda in a Case of Gonorrhœal Rheumatism.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. Waddell (Potter's Bar): The Suppression of Malaria. (The Fellows will dine together at Verrey's Restaurant, Regent-street, W., at 6.45 P.M.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Galloway: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. L. A. Bidwell: The Preparations before Abdominal Operations.

TUESDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Campbell: Consultation. (Medical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—5 P.M. Clinical Lecture:—Dr. C. F. Marshall: Tertiary Syphilides.

WEDNESDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. W. Roughton: Consultation. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Perkins: The Diagnosis of Incipient Pulmonary Tuberculosis.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on *Some Practical Aspects of the Plague at Sydney* (with illustrations). Opened by Dr. F. Tidswell. Among others who are expected to attend are Dr. H. T. Bulstrode, Mr. J. Cantlie, Dr. W. Collingridge, Mr. A. W. Harris, Dr. R. T. Hewlett, Dr. H. F. Parsons, and Mr. S. M. Kaka.

THURSDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Dr. Still: Jaundice in Children.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. L. A. Bidwell: The Treatment after Abdominal Operations.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Surgical Cases. (Post-graduate Course.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical Demonstration.

FRIDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—2-3.30 P.M. Dr. J. Taylor: Class. Clinical Examination of the Nervous System. 4 P.M. Mr. T. Collins: Consultation. (Eye.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *East Daily Press (Norwich), Lancashire Daily Post, Hastings Times, Leicester Daily Post, Liverpool Daily Post, Science Siftings, Court Journal, Alliance News, Midland Counties Herald, St. James's Gazette, Sanitary Record, Invention, West Morning News, Wigan Observer, Daily Messenger (Paris), Birmingham News, Weekly Standard (Blackburn), Sussex Daily News, Yorkshire Post, Times of India, Pioneer Mail, Scotsman, Citizen, Builder, Architect, Leeds Mercury, Denbigh Free Press, Bristol Mercury, Oldham News, Evesham Journal, Sunderland Echo, Rushden Argus, Hertfordshire Mercury, Birmingham Gazette, Stockport Advertiser, Reading Mercury, City Press, Cheltenham Examiner, Oswestry Advertiser, Athenæum, Dublin Evening Telegraph, Accrington Observer, Caterer, Walton Gazette, Middlesex Gazette, Mining Journal, Surrey Advertiser, Local Government Journal, Birkenhead News, West Briton, Stowmarket Courant, Highland Times, Scottish Reformer, Bacup Times, Monmouth Beacon, Lincolnshire Echo, Exeter Gazette, Tenby Observer, Shields Gazette, Carlisle Express, Fleetwood Chronicle, Orkney Herald, Tyrone Constitutional, Western Mail, Haverhill Echo, Lancashire Daily Post, Plymouth Mercury, Bristol Times, Fife Press, Cheshire Herald, &c., &c.*

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, *to whom all letters relating to Advertisements or Subscriptions should be addressed.*

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Harveian Lectures

ON

PROGNOSIS AND TREATMENT IN PULMONARY TUBERCULOSIS.

Delivered before the Harveian Society of London on Nov. 1st, 8th and 15th, 1900,

BY ROBERT MAGUIRE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL.

LECTURE III.[1]

Delivered on Nov. 15th.

MR. PRESIDENT AND GENTLEMEN,—In the previous lectures I asked you to think of the tubercle bacillus in its progress, of how we can estimate its influence upon the lung tissue and the general system, the extent of its progress, and the likelihood of its further action. Now I come to the question of how we can prevent its action and progress and remedy the results of its action. Once more I ask you to think of pathology, for in a perfect knowledge of that must consist not only our prognosis, as heretofore discussed, but also our rational treatment. We must consider (*a*) how we can increase the resistance of the tissues (normally present) to the influence of the bacillus tuberculosis and its congeners; (*b*) how we can hinder the action of the bacillus by destroying its congeners, the staphylococcus pyogenes and the pneumococcus; (*c*) how we can hinder the action of the bacillus by interfering somewhat with its own vitality; and, finally, (*d*) what means can we adopt to kill the bacillus *in situ*?

(*a*) We can obtain increase of the resistance of the tissues by adding to their vital power and this can be done, and has been done since the disease was first known, by over-feeding, fresh air, and adjuvant measures. Before recent agitation we had been doing all this, and I show you here a record from my in-patient department at the Hospital for Consumption and Diseases of the Chest at Brompton of a case, treated on just simply the old lines of care, supervision, good feeding, and especially discipline of habits under a competent sister of the ward. The patient gained in weight 21 pounds in a fortnight, and he is not a very unusual example. Others show similar improvement and that without other treatment which need be considered. The "Open-air Treatment" is, of course, good as adding to the vitality of the patient and increasing the resistance of his tissues. We have practised this, more or less, not only in pulmonary tuberculosis but in other diseases also, long before it was brought before the public so prominently as has been done recently. Debove first advanced the idea of forced feeding. Many had recommended open air in phthisis, and yet let us give honour to the men who systematised the methods. But like all enthusiasts, they were as I think, somewhat wrong. It is right to stimulate the absorptive powers and to encourage them to deal with cod-liver oil, maltine, excessive food, and *so on*. It is right to make the patient breathe pure air, cold air (if needs be), and again to harden himself to exposure—*if he can do so*. But I would like to give you a word of warning. The profession seems to have gone mad on this matter. Remember what Wilkie said about *his* methods. Someone asked him how he mixed his colours so as to get such wonderful effects and he replied, "Juist wi' brains." Mix your prescription of open-air treatment (so called) with a little common sense. Now, is it common sense to make a patient sit down and try to eat another mutton cutlet when he has previously vomited two? Yet I am told that this has been done in a well-known sanatorium and the patient commended for his perseverance. Surely his digestive organs required a little more consideration. And when we know a certain patient to be very liable to the effect of slight chills and also to inflammation as the result of such chills, is it necessary to put him into the open air, covered as it may be from the external atmosphere, but inhaling the cold air into his bronchi, in order to "harden" him? We sometimes cry down the methods of the bone-setters, rightly or wrongly; but surely what I have described savours of them, and I say at once that this idea is wrong. You must mix the open-air treatment and also the treatment in sanatoria "wi' brains" or else leave them alone. But let it not be supposed that I cry down the open-air treatment. I have seen what good it may do with and without the discipline of a sanatorium. I have known what good may be got by it in the best of circumstances, also in such open air as we can obtain in the Brompton Hospital, there, too, with discipline and good feeding; and I have known one patient (whom I saw with Dr. C. F. Knight) to do surprisingly well when dwelling in a tent erected in a back garden in Fulham. But we must remember that all these are only methods of bolstering up the tissues against the bacillary invasion.

Drugs of all kinds have the same effect. So, too, have *other remedies which will be mentioned later*, though their advocates may possibly take a different view of their action. I have used arsenic for many years as a hæmic stimulant in pulmonary tuberculosis and for the reason that, from some cause or other, iron is not well borne by phthisical patients. I have seen good come from its use and I refer to the matter here because of what has recently been said as to cacodylate of sodium being a cure for tuberculosis of the lungs. I have used it and it is useful. It is a good alterative when arsenic by the mouth is not tolerated, and when one wishes to give the same or even an increased dose of the drug by the skin. I have prescribed it in blood diseases and rarely with ill effect, but it acts only as a stimulant to the formation of red blood corpuscles and therefore can only have a very indirect effect upon the tubercle bacillus. It is a useful tonic remedy, and that is all.

Under this heading there may be mentioned my colleague Dr. S. H. Habershon's treatment by the subcutaneous injection of glycogen and that of De Backer by the administration of special preparations of yeast, though the consideration of the latter more properly belongs to a later section. Of these methods I have no personal knowledge and will say little. Dr. Habershon's idea is to increase the phagocytal power of the leucocytes by supplying them with glycogen as a stimulating food, and I hear from him that he has had some encouraging results. He has not yet completed his work but allows me to mention it here. De Backer holds the view that the yeast cells may act as additional phagocytes and absolutely destroy the tubercle bacillus. Allied to Dr. Habershon's method is that of subcutaneous injection of nuclein which will be more conveniently described below.

I cannot within the limits of the lectures discuss with you all the methods of treatment which have been adopted, and most of them discarded, in modern times. I wish to devote the remainder of this lecture to a description of a method of treatment of pulmonary tuberculosis and also of other disorders of the lungs which I have been working at for some time, which is on absolutely new lines, and which I have reason for saying is likely to be successful. I give it now to you for the first time in order that my professional brethren may form an opinion upon it. Its object is to fulfil the indications mentioned under the sections (*b*), (*c*), and (*d*). We would like to kill the tubercle bacilli *in situ* as mentioned in (*d*). But failing that, we may do good by weakening its action (*c*) and so enable the body powers to deal with it more advantageously, and finally, if we can produce no good action upon this very resistent tubercle bacillus, we may be able (*b*) to destroy the more vulnerable assistant germs, the staphylococcus and pneumococcus. What follows I must ask you to consider as a preliminary communication to which details will hereafter be added elsewhere, and I will style the subject

ASEPSIS OF THE LUNG.

It appeared to me that the anatomy of the lung-circulation lent itself to a special mode of treatment. We have seen how successful, and at times unsuccessful, may be the effort to increase the vitality of the lung by excessive feeding, open air, and so on. No pronounced effect is produced on the disease by inhalations of antiseptic vapours, for these cannot be administered so as to pass the glottis in any such strength as could produce effect upon germs, even if the inhalations ever reached the lungs. They do not reach the lungs, for we have reason to believe that they never go much beyond the bifurcation of the bronchi in any appreciable strength. We know only too well, however we may appreciate our successes, that by all these methods we have a lamentable number of failures. The same, I am afraid, must be said of many other methods of treatment which have been put forward at various times and this view I mention with every due respect to the authors of those methods and to the immense amount of work which they have given to the subject. Undoubtedly the rational cure for pulmonary, as for all tuberculosis, is the administration of an antitoxin derived from the tubercle bacillus itself, as was designed by Koch. But, as you are well aware, this has hitherto proved useless and worse than useless. So we must still say of the further attempts in the same line by modifications of his methods. Some day, though probably not in our time, the end thus aimed at will be attained and then we shall have a perfect cure. But before this result is reached we must still go on treating our patients and trying to cure them. Again, attempts have been made to obtain an antitoxin from the growth of the tubercle bacillus, not on our laboratory cultivations, as was done by Koch, but in the living bodies of such animals as the ox, the ass, and the horse. I allude here to the so-called anti-tuberculous serums, all of which have proved to be practically useless. It has appeared to me at times that, seeing how tuberculous patients who suffer from pleural effusion seem to be much better when the effusion is allowed to be absorbed naturally and is untreated by paracentesis—and this you will remember I alluded to in my former lecture—that the good result might be due to the re-absorption of an anti-tuberculous serum grown on human soil. It is not easy to get such serum without doing an injustice to the patient, for, as I have stated, the effusion is best left alone. Yet occasionally it happens that an effusion is so great as to by its actual presence endanger the life of the patient. Such a case occurred to me a little time ago at St. Mary's Hospital and I determined, on removing the effusion, to ascertain whether it possessed any property which was antitoxic to the bacillus. But before using such a serum for experiment it is absolutely necessary to remove from it all active tubercle bacilli, and I could not conceive of any other method of doing this than by passing it through a Pasteur's filter under pressure. But the solution could not by any means be made to pass through the filter and so the experiment had to be abandoned Possibly another chance of which I can take advantage may offer itself in the future. (It may be interesting to record the later history of this case in connexion with the danger from hæmorrhage to which the patient is liable in the third stage and to which I referred at the close of my last lecture. The patient, a youth, aged 18 years, was taken into the hospital because of his effusion and I aspirated his chest though I knew that he had phthisis in the third stage. After a few days he had recovered from his effusion and his phthisis being quiescent I allowed him to leave. He walked from the hospital down Praed-street, was overtaken by copious hæmoptysis before reaching the Great Western station, and was brought back to the hospital dead. I was very thankful that his hæmoptysis did not occur during my aspiration.)

---

[1] Lectures I. and II. were published in THE LANCET of Dec. 1st and 8th, 1900.

I have mentioned the methods of Dr. Habershon and De Backer by which it has been thought possible to inject underneath the skin substances which may reinforce the lung tissue in its fight against the bacillus—namely, glycogen and yeast respectively. Dr. Habershon's work is not yet completed, and I am afraid that De Backer's results must be said to be unsatisfactory. Others, too, have attempted to administer antiseptics by means of the skin—that is, subcutaneously—and without any success. Nor is this to be wondered at when we think that any remedy placed under the skin must be diluted with all the fluids of the body before it reaches the lungs and then cannot fail to be powerless. For many years antiseptics, like creasote and its essence guaiacol, have been given by this method in so dilute a form, to begin with, as to be useless even if applied directly to the bacillus. Yet they are still further diluted in the stomach and more or less altered in their passage through the liver and other digestive organs so as to have not the slightest effect for our purpose when they reach the lungs. It is true that by reason of direct absorption through the blood-vessels of the stomach these drugs—especially creasote, guaiacol, iodoform, and naphthalene, all of which I have used—reach the lung unaltered and can be detected in the expired air. It is true also that these expired vapours are of some slight use in preventing the decomposition of the secreta in the lung. All of these points I have observed and willingly admit. But they have not the faintest direct effect upon the progress of pulmonary tuberculosis; in fact, they are almost useless. It has again been suggested by the followers of De Backer that the yeast-cells, and again other reagents, should be injected directly into the infected parts of the lung; and once more I admit that good results have ensued. But remember, however, that such injections cannot reach very far into the tissues, and they must be very numerous, therefore painful and frequently repeated, if they are to touch even the recognised foci of disease. But what about the unrecognised foci? For surely none of us, however experienced, will venture to say that he can detect by physical examination every spot of the lung affected by an attack of tuberculosis. And what about the patches which, recognised or suspected, are beyond the reach of any injection syringe? Surely there will always remain such spots, inaccessible to all such treatment and ready to spread to neighbouring and other parts of the lung. Such treatment cannot possibly be really curative. And as to the more surgical procedure of removing affected parts of the lung—and this has been done—well, the less said the better, for fear that the mere mention of it may encourage an unduly bold surgeon to practise it.

But let us come back to what I have mentioned above—that the anatomy of the lung-circulation lends itself to our treatment. This has been impressed upon me for some time, for it must be obvious that anything introduced into the veins must necessarily pass directly through the lungs by way of the right side of the heart and without dilution with other fluids of the body than the amount of blood contained in the right ventricle at the time when the injected fluid reaches that cavity. I determined to try this method, and with much trepidation when I thought of the manifest dangers involved in the introduction of a foreign substance into the blood-stream. But I was encouraged to pursue the investigation by hearing that my colleague, Mr. Ernest Lane, had been treating syphilis by injecting 2 per cent. solution of cyanide of mercury into the veins and by seeing the beneficial effects upon one patient of mine at St. Mary's Hospital whom he treated for virulent syphilis. I went to the Lock Hospital to see Mr. Lane's method, and seeing what he had done I thought that if he could inject cyanide of mercury with impunity—for he had done it some 3000 times without other mishap than the occasional missing of the vein by the needle—and seeing, too, that cyanide of mercury was not only anti-syphilitic, but also a powerful germicide, I also might safely use the same on tuberculous patients. Mr. Lane was in the habit of injecting 20 minims of a 2 per cent. solution, but I injected 30 minims of the same solution into the veins of two patients at the Brompton Hospital. But as that strength would be useless for my purpose, and wishing to use the drug in stronger solution, I asked my colleague, Mr. Plimmer, to inject a solution of 5 per cent. into the ear-vein of the rabbit. The rabbit died before the injection could be completed, and, as we found, from coagulation of blood in the right side of the heart. I immediately hurried, as you may readily understand, to see what had been the effect of the weaker injection upon my tuberculous patients and found that both of them had become very collapsed and had suffered from painless diarrhœal flux. It was obvious that what might be safe enough for Mr. Lane's otherwise strong men suffering only from syphilis would not do for my weakly tuberculous patients. Moreover, it seemed probable, though I offer this only as a suggestion, that the mercury of the cyanide combined with the albumin of the blood, causing coagulation and liberated cyanogen and the latter, combining with water, produced a considerable amount of hydrocyanic acid, the effects of which would be to cause vaso-motor collapse and the diarrhœa which was observed.

Let me here say that before using any other remedies and those in any particular strength I was always careful before applying them to patients to test their safety upon rabbits—or later on myself. Rabbits and monkeys are the only animals, except man, which offer suitable subjects for such trials, since their superficial veins can be easily reached without incision of the skin. Obviously, if the intravenous method is to be practised frequently, as it must be for therapeutic purposes, section of the skin by the knife is out of the question, and, indeed, I would incidentally commend to the surgeons the results of technique which I have arrived at in various ways, as being improvements upon the methods hitherto adopted for intravenous injection when employed for other purposes. Again, let me remark that all these trials upon animals were performed by Mr. Plimmer, who possesses—as I do not—the requisite legal permit. Rabbits were used as being cheaper and more easily obtainable than monkeys. Further, before any advance of method was attempted, we tried to inject about 10 cubic centimetres into the ear-vein of a rabbit, that is, five times the quantity I wished at that time to inject into a man, and weight for weight an enormous dose. This having been done with safety I concluded that I was justified in applying the method to man.

To conclude this part of the subject I must here refer to an objection which may possibly be raised in reference to experiments upon animals. It may be asked, Why did I limit myself to merely testing the safety of the various solutions to be mentioned and did not first produce tuberculosis of lungs in the animals and attempt its cure by injection? Here are my reasons. Rabbits and monkeys were the only animals available for this particular purpose and they are very liable to tuberculosis. But it is by no means so easy as you would otherwise suppose to artificially give them tuberculosis of the lungs with certainty. Tuberculosis of any other organ would be of no use for my purpose, for it is only the lungs which are supplied directly with blood from the external venous circulation. Now it is possible to infect a rabbit's lungs with tuberculosis by injecting an emulsion of a culture of tubercle bacillus into the ear-vein. Mr. Plimmer has occasionally done this but never with certainty. The emulsion is prone to coagulate and block the vein and it is very difficult to determine whether a given culture is toxic or not at the moment of injection. I tried to get tuberculous monkeys from the Zoological Gardens, wishing to attempt to cure them; this would I think, be an experiment permissible by the law. But the authorities of the Gardens, who were most courteous to me, naturally did not wish to part with their monkeys until they were practically moribund and useless for any therapeutic effort. Rabbits can be made to suffer from tuberculosis of the lungs by subjecting them to the inhalation of dust containing tubercle bacilli, as has been shown by Cornet. But such infection cannot be done without some risk to other persons than the experimenter. For instance, Cornet himself found that when he entered the room in which the rabbits lived, in order to stir up the dust, and in spite of taking such precautions as plugging his nostrils with cotton wool, nevertheless found afterwards tubercle bacilli in the mucous secretion of his nose. Further, such a series of results as could be obtained in this way would require an almost endless time and far more continuous observation than I could possibly give to them. But, of still more importance to a practising physician, there seemed this objection, that the animals could not tell one how they felt and in human beings we have to consider not only pathological anatomy but many other points in the well-being or ill-being which cannot easily be ascertained from animals. Therefore, I contented myself with ascertaining the safety of such remedies as I wished to apply—from observation on animals and myself—trusting for further results to actual trials upon patients.

Having failed, then, with the cyanide of mercury I cast about for some other germicide. Perchloride of mercury, carbolic acid, and other well-known antiseptics would obviously be useless because of their destructive action upon the blood. I tried, however, upon a rabbit the effect of the potassic iodide of mercury in the way described, for this salt is said not to cause coagulation of the blood. The result, however, was that the rabbit died in about an hour, not from intravascular coagulation like the former one, but from simple poisoning and stupor. Thus far the trials for an intravenous germicide seemed to be futile. I heard, however, from Mr. Wallas, the pharmacist, that diastase had been found to digest cellulose. Now it has been observed that the tubercle bacillus contains grains of cellulose[2] and it is probable that its envelope consists of some form of cellulose. From rough experiments which I made it seemed that diastase had really some power of destroying the tubercle bacillus as it exists in the sputum. This was almost a forlorn hope, but I determined to try the effect of a solution of diastase used intravenously. It was by no means easy to do, for diastase forms a very mucilaginous solution, totally unfit for such injection. Ordinary diastase I found to be quite useless, but it is possible to get a solution of taka-diastase of 5 per cent.—that is, the product known by that name and discovered by Takamine—by growth of germs upon bran. The substance has some undetermined composition, it is certainly mucilaginous, and has a diastasic power. It is of great use, as probably you know, in the treatment of flatulent dyspepsia by helping to digest the starches. It forms with water a thin mucilage which after standing for awhile deposits something which looks like a colloid form of some crystalline substance. After a while, however, a brown translucent fluid is obtained lying over the deposit; this is stable for a few hours, and undoubtedly possesses diastasic properties. But before using this as an intravenous injection it was above all things necessary to make the solution sterile of germs. For this purpose heat could not be employed, for it would destroy the diastasic ferment. The solution was too unstable and too mucilaginous to pass through a Pasteur's clay filter, and, besides, this process would require to be repeated immediately before each injection, which would be impracticable for clinical use. I tried the addition to the solution of such a small amount of perchloride of mercury as would probably act as a germicide. This precipitated the diastase in a few hours, but adding it shortly before the injection I managed to get a solution which would keep for a short time in the fluid condition and this I tried, without ill effect, upon rabbits. Later, Messrs. Squire and Sons prepared for me a fairly permanent solution of taka-diastase made with tri-cresol as the antiseptic, and afterwards with formic aldehyde in the strength of 1 in 250,000. This [illegible] tried upon patients with the view of therapeusis which I have mentioned. I injected 30 minims—that is, two cubic centimetres—at intervals of four days. But the immediate result of the infection (a result which appeared in about half an hour afterwards) was rigor, pyrexia, and sweating; in fact, an exact imitation of an ague attack. The pyrexia reached to the height of about 102° or 103° F. and afterwards the patients felt much better; certainly they took food more freely and there could be no doubt of some improvement in the condition both generally and as judged by the physical signs of the chest. Yet there was not so great an improvement as to encourage me to pursue the treatment. Mr. Horace Brown, F.R.S., so well known for his researches on diastasic zymes, very kindly gave me his advice on the question under discussion and suggested that I should try the effect of cytase, such as he had obtained from freshly crushed oats. He has shown, and has described in his published papers, that this substance is very powerful in digesting the cellulose envelope of cereals. I show you here a solution of cytase which has been prepared for me by Mr. Peter Squire in a form which might be used for intravenous injection, and the solution I have found to have a very definite solvent action even upon cotton-wool. Again, you see under the microscope two sections of barley. One has been treated with a solution of formic aldehyde alone—that is, with an antiseptic; the other with the same reagent, but also with cytase, and the latter specimen shows a marked solution of the cellulose envelope of the grain, while the former appears to be intact. We would like to get the same solution of the tubercle bacillus in the lung, but, unfortunately, the reaction is very slow and is likely to be greatly interfered with by dilution in the process of intravenous injection. I have obtained the solution of cytase which I show you only within the last few days. I will certainly try its effects, for possibly one may be able to hasten its action.

In the last lecture I mentioned the surprising effects which I had obtained by administering nuclein by the mouth in the treatment of such tuberculous glands as could not be removed by operation. I tried nuclein given thus, upon patients suffering from tuberculosis of the lungs, and without the slightest effect. The idea, of course, is that the nuclein will so strengthen the leucocytes as better to enable them to fight the bacillus. But it seemed to me desirable to ascertain what effect the same substance might have when used intravenously. For this purpose I employed the Liquor Nucleinicus of Messrs. Squire and Sons, a sterilised solution of the nucleinate of soda (which I show you), and I injected two cubic centimetres on each occasion. The results were exactly the same as in the case of the diastase solution, a distinct febrile reaction and afterwards some improvement in the condition of the patient but the results were not encouraging, nor do I think it desirable to use a remedy on a tuberculous patient which, like diastase, nuclein, or the tuberculin of Koch, increases, if only for a time, the already existent pyrexia. Yet I think this matter may very well be a subject for future investigation.

---

[2] See Lehmann, Bakteriologie.

The pyrexial reaction after the use of such prospective remedies is very curious and interesting. I may say here, with Dr. Habershon's permission, that in his experiments on the subcutaneous injection of glycogen, he found that the same febrile reaction occurred when the glycogen employed was not entirely freed from nitrogenous matter and did not appear when this matter had been previously removed. Again, during the last few months I have treated four cases of aneurysm of the aorta by the intravascular injection of sterilised solutions of gelatin, following, with some little modifications, Lanceraux's method. After each injection I observed a distinct febrile reaction, the temperature on one occasion rising to 104° F., but always (in these cases) without any inconvenience to the patient. Putting all the results together, one is led to the idea that the fever is dependent upon the introduction into the system, by any method whatever, of some foreign albumin.

But in the course of the above-mentioned experiments the question of antisepsis became, as I have hinted, very important, and I thought that one ought to ascertain whether the results had been produced by the diastase or the nuclein or by the antiseptic used to sterilise the solutions. Mr. Squire told me that he found 1 in 250,000 of formic aldehyde a sufficient antiseptic and this, and afterwards 1 in 100,000, I tried on rabbits and afterwards on patients. I need not give you further details, but let it suffice to say that I at last reached a solution of 1 in 2000 of the pure formic aldehyde gas, that is, 125 times stronger than I had at first used. In my earlier trials I found that I could inject two cubic centimetres of solution in the space of five heart beats, but by later improvements in the technique I could admit into the veins at least one cubic centimetre for each heart beat and frequently double or treble this proportion if the patient could be kept quiet. The reason for measuring the rapidity of injection by heart beats and not by seconds you will see in a few moments. We can calculate with fair accuracy what is the strength of such a germicide solution passing through the lungs when injected into the veins. Using for the purpose of injection the syringe ordinarily employed with anti-tetanic serum, I at first found, as I have mentioned, that I could inject two cubic centimetres in the average course of five heart-beats, meaning that two-fifths (or 0·4) of a cubic centimetre were injected with each heart beat and therefore mingled with each one filling of the right ventricle. The right ventricle of a man who weighs about 10st. 7lb. is believed to hold approximately 100 cubic centimetres, the solution used is of a strength of 1 in 2000, therefore the strength of the solution in the right ventricle will be $\frac{2}{5} \times \frac{1}{100} \times \frac{1}{2000} =$ 1 in 500,000. Not a great strength, it is true, but probably of some efficacy seeing that a certain amount of the reagent will remain in the lung to be added to by future heart beats. Moreover, as I will shortly show you, it is possible by other methods to inject quite easily one cubic centimetre for each heart beat and even twice or thrice that amount. But with the one cubic centimetre for each heart beat we reach a strength in the right ventricle of 1 in 200,000, which is of formic aldehyde a strength which has been proved to be a very efficient germicide. To anticipate, I may say that I have been able to inject 50 cubic centimetres in the space of 25 seconds, when the pulse was beating at only 60 per minute, and even this rate may at times be exceeded. But this speed means two cubic centimetres for each heart beat of a 1 in 2000 solution of formic aldehyde which is added to each filling of the right ventricle, making a solution of 1 in 100,000, which will sluice out the lung for the space of about 30 heart beats. This certainly must be a fairly powerful germicide even for the tubercle bacillus, let alone its more easily attackable congeners, the staphylococcus pyogenes and the pneumococcus. Therefore I determined to use such a solution in the treatment of pulmonary tuberculosis. At first I did not venture to inject more than two cubic centimetres at one time, but becoming bolder I increased the quantity and at the same time the strength of the solution until, by means of the syringe used for diphtheritic antitoxin, I could inject 10 cubic centimetres of a 1 in 2000 solution of pure formic aldehyde gas at one time. Wishing to go still farther I thought it desirable to make the solution of the gas, not with plain water, but with normal saline solution so as to prevent any destruction of the red corpuscles, and it is this solution which I show you now, as prepared by Messrs. Squire and Sons, by their own methods of sterilisation, and called for convenience "Hæmasepsin."

It will be convenient now to describe the method of injection. It seems an easy thing to pierce a vein with a needle and to inject a solution into its interior. In practice it is anything but easy to do so. The vein rolls under the needle and presents great resistance to the piercing. Again, the needle, in spite of all care, will often transfix the vein or at least puncture the opposite wall. In either case not only does the injection fail but the solution is deposited in the circumvenous tissue and causes great pain. It is only after considerable experience and with a certain amount of technical skill that the injection can be properly given, and in view of the manifest dangers no one should lightly undertake it. I find it best first to ligature the arm above the elbow so as to make the veins prominent, and then plunge the needle boldly into one of the large veins on the front of the elbow. The ligature of the arm should now be loosened and the injection proceeded with, carefully watching for any swelling which would indicate escape of the fluid into the circumvenous tissue. I have tried to use a needle on the principle of the Southey's trocar, hoping that on the withdrawal of the point one might easily introduce the canula farther into the vein without risk of re-piercing the wall. This, however, I have not found feasible. Again, I have tried what one might call a valvular puncture—viz., perforating the skin first and afterwards piercing the vein at a higher point. This, however, is difficult to do because of the rolling of the vein—and it must be remembered that any attempt to steady the vein leads to its collapse—and, moreover, there is considerable risk of causing a troublesome hæmatoma in the subcutaneous tissue. For these reasons it is best, I find, to plunge boldly into the vein through the skin, first anointing the skin with carbolic vaseline, 1 in 12. Naturally the needle and the skin must be rendered perfectly aseptic and if the patient be very nervous the skin may be sprayed with a solution of cocaine to anæsthetise it, though this is really unnecessary.

So far, however, the limit of an ordinary syringe—10 cubic centimetres—was reached, and to give larger amounts with one puncture required special apparatus. I therefore devised and had made for me by Messrs. Squire and Co. a syringe (Fig. 1). It is really a miniature stomach pump the tube of

FIG. 1.

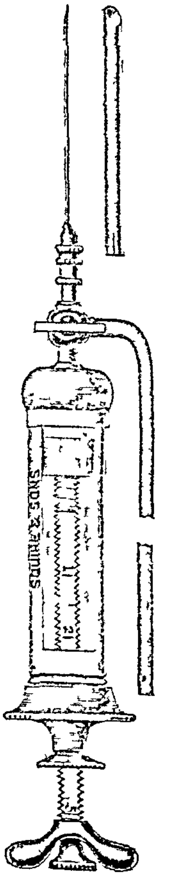

FIG. 2.

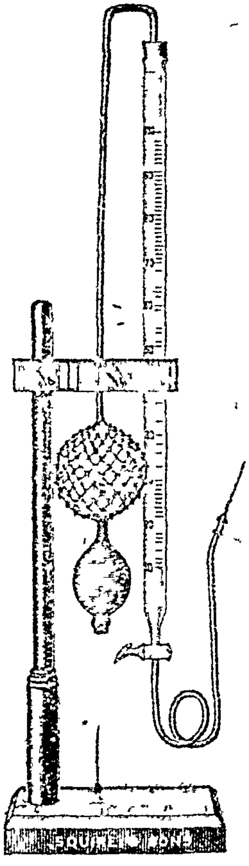

which holds a few cubic centimetres and can be replenished from the bottle without removing the needle from the vein. But this instrument must be used with the greatest care, since the mere movement of turning the stop-cock and reversing the piston is frequently just enough to cause the needle to transfix the vein and ruin the injection. Because of this I have employed mere hydrostatic pressure, using an ordinary 100 cubic centimetre burette of narrow calibre, so as to get as high a head of fluid as possible, and I connected this by an indiarubber tube with a rather wide-bore needle. The burette is furnished with a stop-cock, and the needle being rendered aseptic a certain amount of fluid is run through it so as to fill the whole apparatus with the reagent. I may say here, however, that no fear need be entertained from the entrance of a small amount of air into the veins. This is an old-fashioned surgical fallacy. For ordinary use the burette is the more convenient instrument, though somewhat cumbersome to carry, but occasionally it happens that the venous pressure is so great that the syringe is useful. It was by means of the simple burette and of a large bore needle that I was able to inject one cubic centimetre of the hæmasepsin during each heart beat. Later, however, I have used in addition to the burette the hand-pump you see here, which enables one to make a much more rapid injection (Fig 2). After the injection the needle is withdrawn. A little bleeding may occur and it may sometimes be necessary to cover the puncture with a few threads of alembroth wool and collodion, but commonly the pressure of the finger upon the puncture for a moment or two is enough to stop all oozing. The part is triflingly tender on the next day, but no further ill-effect is usually seen. The slow injection of the solution at ordinary room temperature is accompanied by a curious cramp like pain in the fingers and up the arm as far as the axilla. This I have observed on myself. The pain can be prevented by warming the solution to blood-heat, but I have grave doubts whether this is desirable. The heating may possibly be done with due precautions without destroying the effect of the remedy, but it must be remembered that formic aldehyde is a very volatile substance and the heating of its solution may cause the gas to be driven away. The pain is not great and can really be very easily borne up to the injection of 50 cubic centimetres, so I think it better to give the solution cold; moreover, rapidity of injection almost minimises the pain. In this way by one or other instrument I succeeded in giving daily injections of 50 cubic centimetres without any bad or unduly unpleasant effect. This means, as stated above, that for at least 50 heart beats the lung was sluiced out with a solution of formic aldehyde of a strength of 1 in 200,000 or more. The stronger the solution and the more prolonged its contact with the lung tissue, the more powerful would be its action as a noxious agent on the germs contained in the lung. It was therefore desirable to ascertain the danger-limit of such injection. This could not be found by experiments upon animals—it was scarcely fair to submit a patient to the risk—so I had the trial made upon myself. One morning at about 11 o'clock I asked my house physician, Dr. van Praagh, to inject 100 cubic centimetres of a 1 in 2000 solution of formic aldehyde into a vein of my arm. I wished to ascertain whether the aldehyde passed out of the kidneys as such, and in about an hour it was detected in the urine by the rosanilin test. Incidentally, however, it appeared that albumin was present, but no blood-colouring matter, and that the urine was very acid. Now, at that time of the day the urine of an ordinary man is usually alkaline, and my own is generally so alkaline—as I have frequently observed—as to deposit phosphates at the time of micturition. The ascertained acidity of the urine was therefore abnormal and was probably due to the presence of formic acid, though I had no means at hand for testing this. In about another hour, all these conditions had disappeared. A few days later Dr. van Praagh injected into my arm, and at a somewhat quick rate, 263 cubic centimetres of a 1 in 2000 solution. We only stopped the injection because our stock of solution was exhausted, though I certainly experienced a good deal of cramp-like pain in the arm and a curious nervous uneasiness in the thorax and especially in the cardiac area. Immediately I passed urine which was copiously loaded with blood. Many red corpuscles were found in the urine, but not so many as would be expected from the amount of blood-colouring matter present. An hour later the urine was still more bloody. Then for about four hours it happened to be inconvenient for me to micturate, but on doing so it was obvious that the blood had formed small clots in the bladder, which were expelled only with some straining, and for some little time there was considerable irritation of the bladder. Still later the urine was of a brownish tint containing no ordinary albumin or ordinary blood-colouring matter, but I had no means at hand to collect it or to further ascertain its composition. On the next day all urinary changes had disappeared, but I was very dusky and yellowish as regards the sub conjunctival tissue. During this period, too, I had a certain amount of bronchial catarrh and was conscious too of being unduly irritable in temper. It was here a question as to whether the bad results were due to the formic aldehyde or to the volume of fluid injected, so four days later I determined to have injected a solution of 1 in 1000. This is really (as I found afterwards) a caustic solution and I could not bear the injection of more than 63 cubic centimetres The injection was stopped because of the extreme cramp-like pain and faintness. Very shortly afterwards I suffered from severe bronchial catarrh, accompanied by much wheezing in the chest and the expectoration of considerable quantities of frothy, white mucus. Soon (but subsequently) there occurred catarrh of nearly all the mucous membranes, except, as far as one could ascertain, that of the stomach. There was much running from the nose and conjunctivæ, there was great irritability of the bladder, but no urinary change, and a mild but troublesome dysentery, the bowel pouring forth much clear mucus. On the next morning, too, there was a thrombus in the injected vein of about three inches in length, surrounded by an inflammatory zone and very painful. The thrombus has now become smaller and less painful, but it has not entirely disappeared. This was an unpleasant experience, but it served its purpose and showed that the maximum strength of solution to be employed in its then form must not exceed 1 in 2000 and the maximum injection must not be more than 50 cubic centimetres for an adult.

The experiments showed more. They are imperfect scientifically, for I was not prepared for the result and had not means at hand for its proper investigation. They are sufficient, however, for therapeutic purposes, and naturally I do not care to repeat them on my own person. They show that formic aldehyde is an irritant to the mucous membrane of the lungs and that even after passing through the lungs, its solution may be of sufficient strength to irritate the mucous membranes connected by circulation with the left side of the heart. I have already mentioned what strength of solution we may expect in the right side of the heart from the injection into the veins of a 1 in 2000 solution of formic aldehyde. Naturally this will be enormously diluted by the time it reaches the general circulation and it is difficult to estimate this dilution. But let it be remembered that a dilution insufficient to kill the tubercle bacillus may nevertheless weaken its action, and may still kill other minor germs, such as the staphylococcus pyogenes or the pneumococcus, the presence of which favours the growth of the tubercle bacillus. Experiments are in progress to ascertain the effect of various weak solutions of formic aldehyde on the growth and action of these germs; the results of such experiments I will publish later. Again, let me call attention to the fact that the aldehyde in strong solution caused bronchial catarrh. Below I shall have to mention that cough is not only unrelieved but often increased during the treatment of patients by this method. Possibly such mild irritation may be beneficial as a counter-irritant to the lung tissue, stimulating it to more healthy action, but its existence warns one that the treatment must be pursued with caution and frequent inspection. In fact, I have sometimes found, as I will describe, that improvement only appeared when the treatment had been suspended for a few days.

Again, to prevent disappointment, one ought to remember that the pulmonary artery—the only vessel directly affected by the intravenous injection—is not the only artery which goes to the lungs. As I have elsewhere explained it is the "functional" vessel of the lungs, while the bronchial arteries coming from the aorta are the "nutrient" vessels of the lungs and are not primarily touched by the injection. Nevertheless, I have not found great need for such warning in practice, so great is the diffusion through the pulmonary capillaries.

In estimating the result of such a method of treatment upon the human subject it is of all importance to take care not to deceive oneself. Of, say, 100 cases of early tuberculosis of the lungs probably 90 will show good results with no other treatment than improved hygiene and feeding. If any new treatment were applied to such cases one could easily be persuaded that it was successful. Naturally one would always wish to carry on a treatment in an early stage, but judgment of the effect of such treatment would be futile. For this reason I have only tested the treatment on severe and even desperate cases, thinking it better to meet with some failures if only one could get good results in a few cases where other remedies might have probably been useless. I append a few of such results, to be followed by a further series shortly. The test points are the steadying and reduction of hectic temperature, the quieting of the circulation, the diminution of the amount of sputum, the disappearance therefrom of pus and of the tubercle bacillus and other germs, and the abolition of such physical signs as indicate active tuberculous mischief.

I will tell you, here, the method which I have pursued in testing for such results. In hospital and elsewhere I have treated thus some 50 persons. Some of them were at the Brompton Hospital with surroundings, feeding, and discipline specially designed for their complaint. Others were treated at St. Mary's Hospital with the ordinary course of dietary, &c., pursued in a general hospital. And not all of these had the intensive treatment which of late I have adopted. Dr. R. G. Reid of [illegible]beth has in consultation with me treated some 20 patients who might be considered equivalent to those at the Brompton Hospital, but with their own home surroundings. Dr. A. Findlater of Edgware, who is in charge of the Hendon Workhouse Infirmary, has similarly treated seven cases with practically home surroundings, but also in a country atmosphere, or as near that as one could obtain within easy reach of supervision from London. I must not here give you details of these cases but merely the summary of the results. Almost every case has shown some improvement and in some this has been very marked. Most usually in my own cases the physical signs have diminished in amount as the earliest indication of improvement; appetite and general condition have been better after injection, and in nearly every case the patient has gained weight. The sputum became more frothy and less purulent, and in a few cases tubercle bacilli and other germs have already disappeared. I show you here one such patient. He came under my charge at St. Mary's Hospital in the autumn suffering from a very marked outbreak of the multiple pleuritic form of tuberculosis. His temperature, as you see, showed a rapid decrease, his physical signs diminished, tubercle bacilli disappeared from his sputum, and now he seems to be perfectly well. If you will examine his chest you will find nothing but some thickening of pleura in patches on the left side. Dr. Reid's cases have shown similar results in spite of the somewhat hard circumstances under which the patients were placed. Dr. Findlater, who is here to-night, will tell you himself of his results, one in particular being extraordinary.

The patients should be carefully watched during the treatment, for you have heard how I myself suffered from the effects of an overdose of the injection. If the injection be pursued too long the formic aldehyde will unduly irritate the lung tissue and increase the symptoms. It is only practice and experience which can tell one when to suspend the treatment, but, as a general rule, I should think it desirable to give up the injections for a few days when the temperature has fallen, when the sputum has become mucous and frothy, and when the cough is unduly troublesome. With regard to the latter symptom I do not see the same objection to treating it by opium as obtains in ordinary coughs. This cough is due to irritation of the pulmonary mucous membrane, and the same irritation causes the excessive secretion of mucus. An opiate will relieve both and is not, I think, counter-indicated.

Though it is somewhat outside our present subject, I may here mention the results of the treatment on bronchiectasis. As you know, scarcely anything can have a fouler smell than the sputum from this complaint, and at times so bad is this symptom as to incapacitate the patient from intercourse with his fellows. A patient came under my care at Brompton who had been supposed to be suffering from this, though I found that he really had a tuberculous cavity of the base of the lung with pleural adhesions, which kept the walls of the cavity constantly stretched. This was a similitude of bronchiectasis. His sputum was very offensive, so much so as to render it undesirable to keep him in the same ward with other patients. It separated on standing into the three usual layers. At this time I had not given a greater injection than two cubic centimetres and that by the syringe. After even the first injection distinct improvement was observed in the condition of the sputum. It became almost devoid of odour, less purulent, and much less copious. He left the hospital much improved. I have treated a few typical cases of bronchiectasis similarly and with like, though not such immediate, results. But my last case requires special mention. My colleague, Dr. Percy Kidd, asked me to apply the method to one of his patients at the Brompton Hospital. The patient was a country policeman whose bronchiectasis and accompanying condition were so bad that he had been warned to leave the force if he could not get better. He was really unfit to associate with his fellow men. He had been treated by inoculations in our "guaiacol room," but when I saw him he was in a wretched condition, although he had showed some slight improvement. At this time he was coughing up much more than a pint per day of very foul sputum. I began with the two cubic centimetres of injection on each day and afterwards administered 50 cubic centimetres of injection by means of the burette. He rapidly improved and when I last saw him he was expectorating only three ounces of matter which had only a faint odour. He then had to leave the hospital in order to report himself so as not to lose his pension, but I have little doubt that he could have been permanently cured.

[Since delivering the lectures I have tried, by modifying the vehicle, to use a greater strength of the formic aldehyde solution. At present I will not give details, but I think the result can be accomplished. I purpose bringing the whole matter before one of our societies at an early date in order that it may be adequately discussed.]

ABSTRACT OF THE

Purvis Oration

ON

DIETETIC PROBLEMS.

Delivered before the West Kent Medico-Chirurgical Society on Dec. 7th, 1900,

BY GEORGE VIVIAN POORE, M.D.,
F.R.C.P. LOND.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY COLLEGE, LONDON.

DR. POORE commenced his address by expressing the pleasure which it had given him to accept the honourable duty which the society had asked him to perform, after which he referred to his anxiety first of all to do honour to the senior member of the University of London, and secondly, to do his best to keep up the reputation of the Purvis Oration. He said that he had taken for his subject one that must be in the minds of most of his hearers at the present moment, but he would like at the same time to explain that this particular subject was chosen some months ago and though it happened to be a singularly appropriate one in view of the crisis in connexion with beer that had arisen in some parts of the country, his selection was necessarily made without any reference to that state of things and without any knowledge that such an event was likely to happen. Charles Lamb in one of his well-known essays rather found fault with the members of a certain nation because they were too positive in their utterances. He said that they never seemed to be in doubt; if they were orthodox they were orthodox, and if they were infidel they were infidel, but they never seemed to wander in the dim twilight of dubiety. So far as the West Kent Medico-Chirurgical Society was concerned Dr. Poore deprecated this charge being brought against himself, because it was owing to the fact that the twilight of dubiety had settled upon him in regard to some dietetic problems that he had ventured to address them.

Nothing in this world, he continued, made entirely for good and nothing entirely for evil: roses had thorns and silvery fountains contained mud. We had to balance our accounts and see on which side the benefit lay. Nothing was more remarkable than the change which had come over the dietary of the people of England in the last two centuries At his club the other day he had taken down an old book of household accounts of the sovereigns of England extending from Edward III. to William and Mary, and it was curious to read how limited was the diet of people living in what was then considered to be the lap of luxury. Princes lived practically on fish, flesh, fowl, and beer, and on very little else. It was true that in addition to beer there were other fermented beverages such as wine and drinks made from honey, but many of the articles of diet which we of the present day consider essential were then remarkable for their absence. Sugar and spices were mentioned as real luxuries. Fresh vegetables were hardly mentioned at all, and but for the occasional introduction of pippins, referred to by Shakespeare, there was a lack of almost all fresh fruit. It was hard to imagine at the present day a dietary table without tea, coffee, cocoa, fresh milk, and such like, and without fresh vegetables. It must be remembered how late it was in the history of this country before the potato was introduced into dietetics. It was not till 1767 or somewhere thereabouts that it was introduced into the dietary of St Bartholomew's Hospital. A country gentleman some years ago showed Dr. Poore some old half-yearly rent audit books and on the front page of the books were the summer and winter bills of fare for the feasts which took place at those audits. As late as 1780 no mention was made of the potato. The difficulties a couple of centuries ago in getting fresh meat, and especially fresh vegetables, in the winter months were very great indeed, and it was not until the improvement of agriculture and the introduction of the turnip and other roots as foodstuffs, and the subsequent improvement in horticulture and gardening, that fresh vegetables were at all available for the masses of the people. It could be quite well understood that scorbutic tendencies must have made themselves evident in the winter, and "spotted fevers," and the "purples," and the "bloody flux," and other diseases which had a scorbutic taint about them must have been rife But with the improvement of agriculture and the advent of free trade this state of things passed away. There could be no doubt whatever that the admission of corn to this country free of duty, and food of all kinds at rates against which the home producer was powerless to compete, had improved the dietary of the population at large. When he considered the variety of foodstuffs which were grown in foreign countries and reflected how London was the best mart in the world—one where most things could be got at moderate prices, where bananas were almost as cheap as turnips and pineapples were not the exclusive luxury of the rich—he felt that probably to this fact more than to anything else we owed the approximate abolition of typhus fever, the total abolition of scorbutic diseases, and the general improvement of the public health. Erasmus had said in the sixteenth century that the masses of the British people were fed as well as the monarch, and this remark was not altogether inapplicable at the present day. There must, however, be something that had put a check on the improvement of public health which had undoubtedly taken place, and there were certain facts which must make us pause. One of these facts was the diminution of the birth-rate. Just at present the birth-rate had diminished more than the death-rate, and if we looked at the subject fairly we must see that there must be some lack of stamina in the people at large Another cause for uneasiness was the large number of people living at the expense of others and those who found it impossible at the present day to maintain themselves in a condition of independence. He hesitated to speak of these persons as paupers because the word pauper had a political connexion, but the fact remained that there was an enormous number of people who lived in workhouses, asylums, prisons, and other rate-supported institutions, and the number of such persons seemed to increase rather than to diminish There might be many explanations of this phenomenon, and he was unwilling to speak too positively of its causes. Infant mortality, again, did not show the diminution that was to be desired. The mortality under one year of age was as great as ever and we knew that these children had succumbed to dietetic diseases such as diarrhœa. Rickets was also a dietetic disease, and Barlow and Cheadle had pointed out that scurvy occurred among young children in consequence of dietetic errors. Then, again, women had largely given up the sacred privilege of suckling their offspring and they allowed their children to be brought up on advertised proprietary foods. It was impossible to avoid thinking that the enormous amount of dental caries must be due to some error or deficiency in diet. Most of those who worked in the City of London suffered from dyspepsia, and gastric ulcer was not less common now than it was formerly. Was it not possible that this was also due to some deficiency of diet?

In spite of all that had been done for public health the British constitution seemed very vulnerable to enteric fever, whether in this country or in South Africa, and it was impossible not to mention in connexion with it the insidious increase of malignant disease which puzzled every one. Another subject worth considering was the hand feeding of infants, a difficult question for the solution of which chemistry had been invoked. Attempts had been made to imitate human milk by various manipulations of the milk of the lower animals, but the chemical question was not the only one, for biological and other conditions must influence the digestibility of such milk. He was inclined to think that milk in the mammæ was entirely different from milk *in vitro* When milk was withdrawn from the mammæ it underwent certain physical changes. It was exposed to infection and accidental contamination, its temperature fell, and it began to separate into its constituent parts; moreover, in a few hours it might become sour. Just in proportion to its remoteness from the mother in point of time the milk was more and more unsuited for the nourishment of the suckling. When a young animal was joined to the mother it was joined very much like the bud on the stock. It took in nourishment without exposure to the air or a fall in temperature, and the whole process was altogether unlike the taking of milk from a feeding bottle. Under natural conditions the child sucked a thin stream from the living cells of the mammæ direct into its own stomach, and surely that was a very different thing from taking half rancid food through a rancid indiarubber tube. On this matter we had little positive information, and although obstetricians were quite unanimous that breast feeding was in every way superior to hand feeding still when facts and figures were asked for they were not forthcoming. He had only been able to avail himself of one instance, the data being supplied by a medical friend who had three children, all thoroughly healthy babies. This gentleman had furnished him with figures which showed that two of the children, hand fed, had at the end of 11 weeks gained 37 per cent and 25 per cent. respectively on the birth weight, while the third child, which was nursed at the breast, showed at the end of the same period an increase of 84 per cent. This was very remarkable, especially when it was added to the consensus of opinion in the matter. Of course the use of milk for failing health was common; his hearers would remember that in medical history there were accounts of invalids who had recourse in their extreme old age to the services of a wet nurse, and it is reported that Dr. Caius, the President of the Royal Society, had to be fed in this way. He was rather a petulant old gentleman, but when he got a sweet-tempered nurse his temper completely changed. Many years ago he (Dr. Poore) was called in to see a patient who belonged to the upper classes and who was in a pitiable state, the result of bulbar paralysis. This gentleman was attended by Dr. W. B Cheadle, but about once a month he would become restive and on one occasion he called in Sir William Gull who told him that he wanted a little nourishing food and that at 11 A.M. each day he was to have half a pint of ass's milk with a *petit verre* of noyeau. The ass was driven to the door each day and the patient had the milk hot from the animal. The prescription was entirely Sir William Gull's, but it was represented as his opinion conjointly with those of Dr. Cheadle and Dr. Poore Whether in consequence of the treatment or not the man lived for three years. On looking back at this case Dr. Poore was not at all sure that the prescription was not the cause of the prolongation of the man's life. Much was heard of the dangers of milk, most of which were attributable to the manipulation of the milk itself. Of the disease attributable to the cow we had very little certain knowledge. It had been proved that tuberculosis might be conveyed to the lower animals fed upon milk from a tuberculous udder, but we were very much in the dark as to the part which milk played in the causation of tuberculosis in man.

Evidence on this head ought to be forthcoming before drastic laws were passed regulating the supply of milk. In a herd of cows belonging to the best-known family in this country 38 out of 40 were found to be tuberculous, and this state of things had probably existed for many years. Alongside of this herd was a family of four generations, and as far as he knew there had not been a case of tuberculosis in that family. They should therefore pause before directing that all milk ought to be boiled. Variola and tubercle were diseases common to human beings and to cows. How was it that the variolous cow was at a premium and the tuberculous cow at a discount? He felt that children fed upon boiled milk were likely to suffer in health and that that deterioration in health might lay them open to tubercle. Milk that had been manipulated, whether sterilised or otherwise, ought to be labeled so that all might know what they were buying. Again, a habit was growing up of putting chemicals into the food of children. As a profession medical men ought to resist this. Enough was not as yet known about boric acid and it was disgraceful to make experiments upon babies. With regard to meat he thought that it was best when it was fresh, and most nourishing probably when it was raw. Of late years we had had a revelation in dietetics in relation to the thyroid gland. It was known that when thyroid extract was administered in suitable cases the stunted idiot would grow and develop physically and mentally and the myxœdematous woman would recover her health. That was a most remarkable thing. It was still more remarkable when it was remembered that this power of the thyroid gland was greatly decreased with staleness and was practically abolished by cooking and that the chemist could tell very little about the difference between the cooked and the uncooked gland—the one potent for action and the other that had no action at all. There was a belief, especially among the poor, that beef was most nourishing when raw, and this was probably not mere prejudice. The oyster—almost the only animal food that was taken raw in England—was known to be extremely digestible and stimulating. He reminded his hearers that one of the advantages which the South African Boer had had over us was in regard to his food. With a lump of biltong, the sun-dried flesh of the deer or ox, his commissariat was complete. British officers who had eaten biltong were all loud in its praises. He also referred to the charqui of South America, the pemmican of North America, and the hung beef of Hamburg. When animals were put to stress for food—when, for instance, dogs or cats were about to have puppies or kittens—they were very active in finding fresh food. When he saw his cat hunting for mice or stalking birds in a more than usually active manner he was perfectly sure that there was a litter of kittens in the coal-cellar. His friend Dr. Taylor had been carrying on some experiments for him with regard to the digestibility of muscle. The fresh quivering muscle of a rabbit, muscle in the condition of rigor mortis, and muscle when the rigor mortis had passed away, were respectively put into similar mixtures of pepsine and hydrochloric acid. In the fresh muscle the digestibility was 25 per cent. more than in the other samples. They seldom ate food that was absolutely fresh. To show that absolutely fresh food could be eaten with relish he instanced a case in the war in South Africa A herd of deer were surrounded, killed, skinned, cooked, and eaten at once. It was an interesting thing to note that it was said that a coursed hare could be eaten on the same day that it was coursed, but on the other hand a hunted stag was an impossible food. He mentioned this because it was one of those things of which he should like to have more knowledge. Finally he asked what it was that happened to meat when it was hung and ripened? He could not give the answer, but he strongly suspected that there was a microbial action concerned. It was the cultivating medium which stimulated our appetite.

They were apt to look too much to chemistry in the matter of food. Who when they ate considered whether they were taking too much carbohydrate or too much proteid? It was what they digested that did good, and this depended on whether it was savoury and stimulating to the glands of the palate and so forth. If a person sat down to a repast selected so as to contain a certain percentage of proteids it was very likely that the stomach would rebel. He thought that there was too much of this sort of thing and that physiological chemistry was doing itself no good by it. He could not help thinking sometimes that there were manufacturing firms who kept chemists very much as advertising tailors used to keep poets and for the same reason. In conclusion, Dr. Poore referred to "shop eggs" and to the difference between fresh and frozen meat. He also gave a humorous account of a visit to a village on a Saturday night where the grocers' shop-windows were filled with potted vegetables and where the smell from shops in which slabs of semi-transparent flabbiness were frying in oil could be appreciated a quarter of a mile away. Replying to a note that was handed to him asking for his opinion on the doctrine of not taking any meat, he said, "All flesh is as grass."

THE CONDITION THREE YEARS AFTER OPERATION OF FIFTY SUCCESSFUL CONSECUTIVE OVARIOTOMIES;

FIVE PATIENTS LOST SIGHT OF, 32 IN EXCELLENT HEALTH, SEVEN CASES NOT QUITE SATISFACTORY, THREE UNSATISFACTORY, AND THREE PATIENTS DEAD.[1]

(Notes of some cases refused operation and of the author's unpublished fatal cases of ovariotomy are added.)

BY JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE statistics of ovariotomy have been made a subject of competition amongst surgeons, and it may be admitted that when the operation was new and its mortality was great the rivalry served a useful purpose, but now that the mortality is small the announcement that one has attained the lowest death-rate is apt to prove misleading; for the fact that a surgeon is able to publish a series of 50 consecutive recoveries from ovariotomy has not necessarily any scientific or clinical value. Even a much larger number of consecutive successes might be recorded without proving any special skill in the surgeon, whilst, on the other hand, there might be no discredit to an operator in the occurrence of fatal cases under his care at short intervals. The man who has the lowest death-rate is not by any means necessarily the best surgeon. The mortality is influenced to a considerable extent by two factors which are quite independent of surgical skill. One of these is chance. A surgeon may have a long series of simple cases or of difficult cases, and this factor cannot be eliminated altogether in any number of operations. It is obvious, however, that a man who has the opportunity of performing ovariotomy very frequently is likely to be asked to undertake an undue proportion of operations that are difficult and dangerous, so that his death-rate might possibly be increased in consequence of his recognised ability. It is also obvious that if a surgeon selects a series of cases from his work, as I have selected the cases which form the subject of this paper, the results recorded may offer no indication of his true death-rate. A brilliant series of successful cases may by chance be part of a very poor record.

Another factor which influences the death-rate is the care and skill with which the cases for operation are selected. Some of the authors of statistical papers on ovariotomy have asserted that they made no selection of the cases operated on. I do not understand such an assertion. Every surgeon must select his cases. It is hardly possible that a surgeon could see a large number of patients with ovarian tumours without meeting with a malignant ovarian growth which he could not remove. If he has met with such a malignant case and has not operated on it, whilst asserting that he has made no selection of cases for operating, he really makes an unjustifiable claim.

I have elsewhere pointed out[2] that a statistical paper on ovariotomy has little or no value unless it is accompanied by an account of the cases simulating those of ovarian tumour in which the surgeon has declined to operate, but I do not know of any series of cases in which this plan of publication has been adopted. In the series which I am now about to consider there are three cases in which the mistake of refusing to operate was very nearly made, and in two of them operation was delayed for a considerable time because of errors in diagnosis. In one case I thought that the tumour was malignant, but on exploration of the abdomen I found a simple ovarian cystoma. In a second case a soft fibroid had been diagnosed four years before I operated. In the third case I opened the abdomen thinking that the patient suffered from chronic inflammation of the ovaries and Fallopian tubes. She had been under my observation as a hospital out-patient for many months, operation having been postponed from time to time after consultation with my colleagues. These cases might easily have passed out of my care, and indeed the second and third had passed out of other hands before I saw them. From this it is obvious that I may at times have seen cases of ovarian tumour without detecting the condition, and of course other surgeons may have had a similar experience.

---

[1] A paper read before the Medical Society of London on Dec. 11th, 1899.

[2] Illustrations of Some Modes of Death after Ovariotomy, Transactions of the Royal Medical and Chirurgical Society, vol. lxxviii.

Apart from cases in which the existence of an ovarian tumour is uncertain there are cases, such as two of those recorded at the end of this paper, in which ovarian neoplasms are diagnosed, but it is doubtful whether the patient has any chance of recovering from the operation of ovariotomy. Under such circumstances surgeons may come to different conclusions as regards the advisability of interfering; some holding that an operation is useless and therefore should not be performed, others maintaining that the boldest surgery is justifiable because cases of ovarian tumour complicated by very serious exhaustion or other adverse conditions are almost invariably fatal if left alone, whilst the patient may sometimes be restored to long life if her tumour is successfully removed. Clearly the decision which is come to in such cases must influence the death-rate, and therefore some record of cases in which ovarian tumours are known to exist or in which they might possibly exist but in which no operation had been performed, is essential if the publication of the statistics of ovariotomy is to have any scientific value, or any value for comparison with the statistics of other operators. It is obvious that a man who is keen to exhibit a low death-rate must tend more or less strongly to avoid operating on serious and dangerous cases. Quite apart, however, from any idea of future publication, every surgeon, I think, must have occasionally felt some hesitation in recommending and undertaking an unusually hazardous operation immediately after a similar case has proved fatal in his practice, or after a run of bad luck. That the treatment of a particular patient may be influenced by the state of a surgeon's statistics at the moment when he gives his opinion, is a possibility which should be eliminated by every available means; but undoubtedly the practice of publishing and comparing statistics, without giving any details of similar cases in which operation has been refused, tends to intensify the influence of the surgeon's personal, even if temporary, feelings on his treatment.

There is another very important and serious objection to the practice of publishing and comparing statistics of ovariotomy—namely, the fact that the figures are not all drawn up according to the same plan. Some surgeons have set aside in supplementary lists those cases in which the operation is incomplete or otherwise complicated: I have never been able to see any justification for this method from a scientific point of view, and from a clinical point of view it seems to me simply misleading to exclude incomplete or complicated cases from statistical tables. By such means it is possible to modify the death-rate to a very large extent. Take, for example, the six fatal cases which I reported in the Transactions of the Royal Medical and Chirurgical Society, vol. lxxviii. These were all of my fatal cases of ovariotomy at the time of publication. Two of them were incomplete and two were complicated by hysterectomy; and for these reasons they might have been put in supplementary lists and excluded for purposes of quotation from my death-rate. In the fifth case the tumour had already been explored by abdominal section by one well-known surgeon and another surgeon had refused to operate on it before I saw the patient. I completely removed a papillomatous tumour and the patient survived 35 days, death being then due to obstruction of the bowels. I attributed this obstruction to the irritation of serous exudations and of frequent tappings which had induced extensive adhesions. There is no doubt in my mind that I did right in removing this tumour, and that both from a scientific and from a clinical point of view the case should be counted amongst my fatal ones. But for purposes of comparison with other statistics this case might fairly be set aside by me or it should be carefully referred to by the other gentlemen concerned when their statistics are published. The tumour ought to have been removed when the abdomen was explored 18 months before I operated, and the chances of success would then have been far greater. Thus, for purposes of quotation, five out of six deaths might have been removed from my death-rate. The sixth death was due to a uterine condition, and it also might have been excluded from my statistics without much ingenuity, leaving no mortality. Some such manipulation would have been necessary to get a fair comparison with many of the published tables, but all six patients died after ovariotomy or attempted ovariotomy, and I repeat that I have never been able to understand why each one should not count as a death in my statistics. Any other plan would amount to this, that in publishing statistics a surgeon may determine that certain cases in which he has removed an ovarian tumour or part of one are not to be considered cases of ovariotomy, and, if the patients die, they are not to be counted as fatalities in his statistics of this operation, he alone being the judge as to which are to be eliminated. This method of setting aside and excluding from the death-rate cases in which ovarian tumours have not been completely removed has, unfortunately as I think, received the support of men of very high standing; but if cases in which the surgeon has failed to complete his operation may be excluded from statistics, another surgeon might with equal reason exercise his ingenuity in proving that his patients died from complications, and not from ovariotomy. Thus the statistics of this operation might eventually depend, and do now to some extent depend, on a skill and ingenuity which are certainly not surgical.

It is not always easy to say whether the death of a patient is caused by an operation or not. For instance, a patient may get pneumonia and die a week or 10 days after a simple ovariotomy in which otherwise everything has gone well. Perhaps no one is in fault, and it may be abundantly clear that the death is not attributable to any want of skill or care on the part of the operator. It would be hard on a surgeon who was collecting statistics for purposes of comparison to have to include such a case amongst his deaths. Nevertheless, in the circumstances suggested it is fairly certain that the patient would have escaped the pneumonia if the operation had not been performed, and although it might possibly be argued that a death from an intercurrent disease should be excluded from the surgeon's statistics, because there is no necessary connexion between the operation and the death, it is also quite certain that in excluding such cases when quoting a death-rate to a patient the surgeon would conceal a risk which the patient must undergo if ovariotomy is performed.

Again, it is sometimes not possible to say whether an operation is an ovariotomy in the sense of *removing an ovary for new growth* or not. At the end of this paper I shall refer to a fatal case in which I am not prepared to say definitely whether I removed a suppurating ovarian tumour or an abscess of the ovary. In publishing this case a surgeon might fairly choose to put it amongst his operations for new growth or amongst those for inflammatory disease, but for scientific and clinical purposes it would be better to refer to it in the statistics of both these operations.

A fatal case which I shall hereafter record illustrates a fallacy seldom noted in statistics. It was first diagnosed as an ovarian tumour but the disease was really a severe pelvic inflammation. When an ovarian tumour is diagnosed the possibility that the disease may be something else always exists. There are some conditions, such as those found in certain cases of retro-peritoneal cysts and in some cases of cystic uterine fibroids, which it is quite impossible to differentiate from ovarian tumours before the abdomen is opened. Thus the risks run by a woman who is advised to have an ovarian tumour removed include those which may arise in case some other condition is found. Some of these conditions are easily dealt with by an experienced surgeon, so that possibly the average risks may not be greatly, if at all, increased by this possibility of a mistake in diagnosis being made. In one instance, however, that subsequently came under my care, a cystic fibroid tumour of the uterus had been cut down upon and the scar of the incision was 14¾ inches long when I measured it. A tumour of this kind always grows, and therefore ought to be removed, but the operator neither removed it nor told the patient to seek further advice, and an interval of two years and eight months elapsed before she came under my care, when I performed successfully a hysterectomy, which was really a very simple operation. The case shows that the risks run by the patient in case of a mistake in diagnosis may be very considerable.

Owing to such considerations as the foregoing I have never paid much attention to statistics either in my work or in publishing an account of it. The majority of statistical papers concerning ovariotomy, especially those of recent date, seem designed chiefly to show the best side of a series of cases and if possible to beat the record as regards recoveries. The fatal cases which occur in every practice, if it be long enough, are, however, the really instructive ones. I have therefore published most of the deaths from ovariotomy and from attempted ovariotomy which have occurred in my practice, and I propose to relate those not yet published at the end of this paper.

My object in the present communication is to record the condition of a series of patients three years after the last operation of the series was performed (Oct. 2nd, 1896), and I have chosen 50 successful consecutive cases because they seemed to give a better foundation for a paper than a series in which there were some deaths from operation. I shall say little about the simple and satisfactory cases, but I shall record certain accidents and mistakes that occurred, and I will give a more detailed account of those cases in which the later condition is unsatisfactory or not so satisfactory as might be desired. Deductions from a comparison with the statistics of others would be utterly illogical, for it is practically impossible that another series of 50 cases could occur in which the initial conditions would make such a comparison useful in any way. Details of the operations and of the convalescence of the patients will be referred to only in so far as they seem important in connexion with the more recent conditions to be recorded.

Four cases in which operation was refused during the period covered by the 50 cases under consideration.—Before discussing the 50 cases referred to in the title of my paper I propose to fulfil the conditions which I have laid down as necessary in a statistical paper by recording shortly the cases which I saw during the period covered by the series under consideration, and concerning which I was conscious that I might possibly have made a mistake in refusing to remove ovarian tumours. These were four in number.

The first was the case of a hospital out-patient whom I was asked to examine by my colleague Mr. A. Corrie Keep. She was an elderly woman, who had an abdominal swelling which I diagnosed as a malignant ovarian tumour which I could not successfully remove. The inguinal glands were enlarged, and the tumour was firmly fixed in the pelvis. As the bowels were much loaded I advised that the patient should take some laxative medicine and be examined again later. She did not come back to the hospital and I have no knowledge of her subsequent history.

The second case was sent to me by the late Dr. R. E. England of Dover. The patient was a woman, 47 years of age, from whom Dr. Pregaldino of Ghent removed an adeno-carcinoma of the right ovary in November, 1894. On Oct. 8th 1895, she consulted me, and I found a tumour, partly solid and partly cystic, which projected freely into the vagina to the left of the cervix uteri The tumour extended along the left side of the uterus above the pelvic brim. The uterus was easily defined beside it, although firmly fixed to it, and the growth was so closely adherent to the pelvic wall that I thought that any attempt to remove it would end in failure. I therefore advised that no operation should be performed and the patient died nine months after I saw her. This is the only case I have seen in which a tumour that I believed to originate in the ovary sprouted freely into the vagina.

The third case was one in which I opened the abdomen on Jan. 14th, 1895. I found a tumour of the left ovary which was extensively adherent, but seemed as if it might be removed without much difficulty. Another tumour on the right side was firmly adherent to many coils of small intestine. The most easily reached of these coils had new growth penetrating its wall and protruding into the lumen of the gut. I did not persevere with the operation because a resection of bowel would have been necessary and there were many adherent coils behind, any or all of which might have required similar treatment. The patient recovered, but I regret that I have lost all trace of her.

In the fourth case in which I did not operate an abdominal growth and a uterine growth were discovered in a patient 50 years of age. The patient had a great deal of offensive discharge from the vagina and the uterine cavity was dilated and curetted in order to determine the nature of the uterine disease. A malignant uterine growth was diagnosed, but the case was not considered suitable for hysterectomy. After the exploration there was an irregular temperature with abdominal distension and pain. The gentleman who had curetted the uterus thought that the patient had an ovarian tumour with a twisted pedicle in addition to the uterine disease, and he asked and urged me to open the abdomen. It seemed to me, however, that if the uterine condition were malignant the abdominal tumour was also malignant and that the patient was suffering from an inflammation spreading to the peritoneum from the recently disturbed intra-uterine diseased tissues. Under the circumstances I considered operative treatment quite hopeless. I therefore declined to interfere, and the patient died. At the post-mortem examination a ruptured ovarian cyst was found with acute inflammation of the peritoneum in its neighbourhood. There was no twist of the pedicle. There was no malignant disease, but the uterus was affected by fibroid neoplasms, some of which had sloughed. The two questions of diagnosis which arose in this case are occasionally a source of very great difficulty. I was not in any way responsible for the diagnosis of malignant uterine disease; but some 12 or 13 years ago I saw a somewhat similar case in which I did not know what the patient was suffering from. I consulted a man of far greater experience than my own, and he said without hesitation that the patient had a malignant growth of the uterus, a diagnosis which I accepted. A few days after our consultation I was sent for because the patient could not pass water and was in great pain. She was in bed, and I suggested that she should try to pass water in the erect position. The bladder acted without difficulty, and the patient at the same time expelled from the vagina a putrid fibroid tumour of oval shape measuring nearly five inches in its greatest length. After that she rapidly recovered her health

In cases of doubt between malignant disease in the abdomen and an ovarian tumour, either on account of twisting of the pedicle or of rupture of one or more cysts, it is only by opening the abdomen that it is possible to make the diagnosis certain. But if this question should be placed before me again in a patient whom I believed to be suffering from malignant disease of the uterus, with peritonitis developing soon after the uterus had been disturbed by exploration, I doubt if I would operate unless it seemed feasible to remove the uterus also.

Five cases which have been lost sight of.—As regards the 50 cases now under consideration, I regret that there are five of them which I have been unable to trace. Their histories are shortly as follows:—

In the first of these cases the patient was a married woman, 40 years of age. She had noticed a tumour for nearly two years. I removed a multilocular ovarian cystoma which distended the abdomen as high as the costal margin. There were some very vascular adhesions to the pelvis and bladder, but the highest temperature during convalescence was 100·6° F. in the vagina, and after three days the temperature was normal. The patient left the hospital on the twenty-third day after the operation.

In the second case the patient was a widow, 60 years old, who had a large cystic tumour filling the abdomen. The tumour was deeply buried in the left broad ligament, and the sigmoid flexure was pushed high up in the abdomen by the tumour, to which it was firmly attached. There were some omental adhesions, but the chief difficulty lay in the deep enucleation from the broad ligament. The Fallopian tube formed a loop six inches long on the front of the growth, the fimbriated extremity being within an inch of the other end of the tube. The uterus was atrophied, and I could not discover the right ovary. The highest temperature during convalescence was 100·8° F. in the vagina, and the patient left the hospital on the twentieth day after the operation, being then very well.

The third case was that of a neurotic single woman, aged 33 years, who had a very tender tumour of the size of a duck's egg on the right side of the uterus. The pain made her quite unfit for work during four days of each period At the operation there was no difficulty except that the ovaries had very short pedicles. There was a small fibroid tumour on the right side of the fundus of the uterus. Both ovaries were removed. The right was cystic and the left contained a dermoid cyst about three-quarters of an inch in diameter. During the first week of convalescence the temperature once rose as high as 101° F. in the vagina, the pulse at the same time being 70. The temperature came well down to normal, but on the tenth day there was a sharp rise to 102·2°. Apparently this thermal disturbance was connected with the administration of a purgative. At this time the pulse did not rise above 72 and the temperature was again normal two days later. The patient left the hospital on the twenty-first day after the operation and she was then in very good condition.

In the fourth of these cases the patient was 26 years old. I diagnosed and removed an extra-uterine pregnancy of the size of a large Tangerine orange An ovarian tumour of somewhat smaller size was also removed The highest temperature during convalescence was 101° F. in the vagina. The patient left the hospital on the twenty-first day after the operation, the temperature then having been normal for a week.

The fifth case was that of a married woman, aged 27 years. The patient had been told that she was pregnant, although her menses had not ceased and there was no enlargement of the mammæ; but the abdomen was as large as if it contained a uterus at the seventh month of gestation. The patient was very feeble, with a weak pulse, and a loud hæmic murmur was heard all over the cardiac area. She was much afraid of the operation. I removed over three pints of ascitic fluid and a solid ovarian tumour weighing 2 lb. 14 oz. Mr. Targett examined the growth and informed me that it showed no evidence of malignancy. This patient had an attack of bronchitis and a high temperature for nearly a week after the operation. On two nights the temperature was as high as 103 4° F. in the vagina, and the patient's condition made me very anxious, but she slowly regained her strength, and about 18 months later she was very well. Since that time I have not been able to trace her

In the remaining 45 cases, 32 of the patients seem to me to be in really good health; seven others have very little to complain of; three are in an unsatisfactory condition; and three are dead.

Thirty-two patients in really good health.—In 1887 I argued that the recovery of a patient after an abdominal section depends to a very great extent on the success with which the surgeon prevents intestinal troubles, and I showed that intestinal difficulties due to paralysis of the bowel and obstruction of the bowel had been generally mistaken for inflammatory conditions of the peritoneum. The views I then published are now universally regarded as correct, and the importance of paresis of the bowel as a factor in bringing about symptoms of obstruction after an abdominal section is insisted on by all who write on this subject. I would on this occasion further point out that not only the immediate result of the operation but also the future health of the patient is largely influenced by the extent to which the functions of the intestines are unimpaired or are interfered with by peritoneal adhesions. If adhesions exist in such positions that the propelling effect of peristalsis is hampered in any way they may induce much pain, constant indigestion, and a permanent liability to symptoms of intestinal obstruction of an acute or chronic character. It is an important fact that intestinal adhesions may stretch or become absorbed so as to give less trouble as time goes on. To such changes I attribute the fact that a number of the patients whom I now report as in every way satisfactory complained of bowel difficulties for varying periods after their operations.

It is not safe, however, to count too confidently on the disappearance of adhesions. I have evidence that they may be persistent for many years after an operation, and there can be no doubt that they may continue indefinitely. Hence, if an acute illness, with intestinal difficulties that might be due to an obstruction by band, arises at any time after an abdominal section has been performed, the fact that these symptoms may be due to adhesions should be kept prominently in mind. Under such circumstances I would urge that all the arguments in favour of immediate operation should be considered as of unusual weight. I have been forced in consultation to delay operation in two cases of this kind. In both death was proved to have been brought about by an obstruction caused by an adhesion. Neither of the patients had the slightest chance of recovering without an early operation, but one of them would almost certainly have recovered if she had been operated on when I first advised interference.

It is to be expected, therefore, that the best results after ovariotomy will be obtained in those cases in which the tumours have no adhesions and require no enucleation from the broad ligaments. If I put on one side the five cases which were lost sight of and the three cases in which the patients have died; I find that in 15 of the remaining 42 cases there were no adhesions, and no enucleation of the tumour was required. In 12 of these cases the present condition of the patients is thoroughly satisfactory. In 27 cases the operative difficulties varied from the slightest adhesion to complete union of the tumour to all neighbouring structures, and in some cases a very deep enucleation from the broad ligament was necessary. Of these 27 patients 20 are quite well. Thus in this series the proportion of really satisfactory cases did not greatly differ whether there were adhesions or not before the operation; but in the three cases which are not quite satisfactory after simple operations the patients have little to complain of and might very possibly have been quite as uncomfortable if they had never developed tumours requiring removal by operation, whereas in the seven not quite satisfactory cases in which adhesions were found three of the patients are now not at all as I would wish them to be

Numerous adhesions do not, however, always lead to bad results. They cause no harm when the adhesions do not interfere with the function of the bowel. For example, the intestines in cases of tuberculous disease may be almost or quite universally adherent and yet bowel symptoms are not necessarily prominent. One of my cases in which adhesions must be numerous has already been published[3] The tumour was an unusually adherent dermoid cyst and the patient during convalescence gave no cause for anxiety for 16 days. She was then allowed to get up and symptoms pointing to the existence of a pyonephrosis gradually developed; the patient became very ill, the temperature rose to 105° F., and she appeared to be dying On the twenty-seventh day after the ovariotomy I incised the left kidney, which was very much enlarged, but I found no pus. Nevertheless, this second operation was followed by an immediate improvement and convalescence progressed favourably, being interrupted only by occasional attacks of pain and high temperature, which, however, were always relieved by purgation. The loin wound closed and in July, 1897, 13 months after the operation, I reported that the patient's health was thoroughly re-established. She still has occasionally a little pain which is relieved by the administration of laxatives. She can walk as well as can most of her friends, but she has not ventured to ride a bicycle or to take horse exercise, to which she had been accustomed. (Since the above was written the patient has told me that she is in excellent health.)

Within three weeks of the operation last referred to I removed another dermoid tumour from universal adhesions. These two operations were very similar, the patients being 32 and 35 years of age respectively. The second patient has also had occasional pains, which have been relieved by rest and laxatives, and she can now do everything she wants to, with the exception that if she stands for any length of time she becomes very tired. She can, however, ride a bicycle and skate freely without the slightest trouble. In both these cases it is fairly certain that a great deal of adhesion of the intestines still exists, the tumours having been literally peeled out of strong inflammatory attachments. Both growths were very hard, heavy, and irregular in outline, with many bony parts projecting under the surface, and the adhesions seemed to be due to the mechanical irritation caused by the rough surfaces, for one tumour had no twist of its pedicle, and the other had only the slightest turn, which was not sufficient to obstruct its blood supply. Of course it is impossible to say positively that these patients have any adhesions now, but recently I have performed second operations on two very similar cases, with intervals of 18 months and four years and three months respectively after the first operations, and in each of them adhesions were very numerous, firm, and extensive, around the site of the first operation Patients with such extensive adhesions, if they recover well from the operation, are more free from danger of serious trouble than they would be with one or two isolated bands of adhesion, because the danger of an obstruction arising after the patient has completely recovered from the operation is much less when a large area of intestine is fixed than it is when the intestines are for the most part freely moveable and are held firmly at one or two points only.

The history of another patient in whom no adhesions were found at the operation shows that bowel difficulties do not always depend on adhesions, but may be caused by a sluggish peristaltic action, such as may be found in patients who have not been operated on. This woman was 36 years old and had suffered from severe constipation for many years, for which horse exercise had proved very beneficial. This kind of exercise had to be discontinued when the patient's abdomen became of great size from the development of two ovarian tumours. For four months before the operation the constipation was very obstinate; and during convalescence the patient was much troubed in this way until I allowed her to resume horse exercise, when the bowels acted more satisfactorily, and she very soon reported herself as quite well.

---

[3] *Twenty six Cases in which an Abdominal Section has been performed a Second Time*, Transactions of the Medical Society of London, vol. xx., Case No 20, p. 26.

Some of the other cases that have made good recoveries have points of interest. In one I opened the abdomen, letting out much fluid which I thought was free in the peritoneal cavity. I tapped a very soft, friable, multilocular cyst, and then found that I was working within a thin-walled cyst and that I had tapped a secondary cystic growth. I was not able to separate the main cyst from the peritoneum of the anterior abdominal wall at the site of my incision. I therefore cautiously opened the cyst behind and exposed the small intestines which were only slightly adherent to the tumour. I was then able to separate the cyst from behind forwards. It was very thin-walled and firmly adherent to the liver and to the peritoneum of the anterior abdominal parietes. The patient, who was 23 years of age, had an extreme lateral spinal curvature and was very delicate. She had worn a spinal support from childhood. The enlargement of the abdomen caused by the tumour had been noticed only six months before she was sent to me. This operation was a very dangerous one on account of the extensive tearing of tissue that was necessary and the feebleness of the patient. So far as the operation is concerned, however, the result is perfect and since she left my care the patient has been able to dispense with her spinal support.

In four of the cases an ovarian tumour had already been removed at an earlier date. In one of these the bowel was injured at the second operation, but the result is very satisfactory. Mr. Knowsley Thornton removed a tumour of this patient's left ovary in 1882 and on Nov. 18th, 1895, I removed a tumour of her right ovary of the size of a small orange. This was deeply embedded in the right broad ligament with coils of small intestine firmly adherent to its posterior and upper surfaces. In order to make sure that the intestines were not punctured in removing the tumour I had to separate a large mass of matted small intestine which was firmly adherent in the pouch of Douglas. The walls of the intestine were torn in many places and at one point its lumen was opened. The perforation and many other injuries of the parts were sewn over with Lembert sutures; the patient made a good recovery and is now, four years later, quite well. As a rule it is not wise to meddle with extensive adhesions which have caused no symptoms of intestinal obstruction, but sometimes, as in this case, the surgeon has to effect a partial separation and then it may be wiser to proceed to divide all the adhesions. There is no more difficult question than to decide how much should be done in this way.

In one case of the series, owing to a mistake on the part of a nurse in counting the sponges, I left one in a patient's abdomen and removed it half an hour after she was put to bed. She also is quite well and the incident of the sponge gave rise to no trouble.

On one occasion I removed a cystic tumour of the left ovary and found a small horn like growth on the right ovary. As the disease on the right side seemed to be confined to a small portion of the gland I removed the new growth with a wedge-shaped portion of healthy tissue and sewed the parts together by means of fine silk, leaving the greater part of the ovary. This patient writes that she has since been in good health.

The following case was reported as untraced when this paper was read. The patient was a single woman, 23 years old, and I diagnosed an ovarian tumour deeply buried in the right broad ligament. On opening the abdomen I found, as I thought, a tumour closely attached to the right side of the uterus. The uterus seemed to stand out so well to the left of the tumour that I expected the latter when tapped to shell out of its capsule easily and I therefore tried to complete the operation through a short incision. After tapping, however, I could not quite understand the conditions and on enlarging the incision in the abdominal wall I found that I had tapped the pregnant half of a double uterus. I very carefully closed the punctured opening. There happened to be a small cyst of the right ovary which I removed and the existence of which brought the case within the series under consideration. The patient, of course, miscarried and I had to scrape away the placenta and membranes, but she made a good recovery. I lost all trace of her until February, 1900, nearly four years after the operation, when I heard that she had been delivered of a seven and a half months child in a lying-in hospital. The resident medical officer of that institution has kindly informed me that when she left the hospital the whole uterus was larger than normal and that at the fundus it was possible to distinguish the left uterus, which was softer, from the right, which was smaller and firmer. The septum of the cervix was easily felt, the left os uteri being the more patulous. (Mr. Corrie Keep informs me that this patient, who had been under his care before I saw her, had been pregnant on a previous occasion—a fact which I did not know or had forgotten.)

There is one other case that should be mentioned amongst those in which the results are quite satisfactory. The patient had a dermoid tumour of very irregular shape, which was deeply embedded in the right broad ligament and which was diagnosed by myself and others as a fibroid uterine growth. Before and for months after the operation I found granular and epithelial casts in the urine which was pale and was passed in large quantity. Its specific gravity was never above 1010 and it did not contain albumin. Five months after the operation the patient had an acute attack of nephritis, with much blood in the urine, but she is now in a very satisfactory condition; she looks well, does a great deal of work, and has not required medical assistance for nearly three years. A specimen of her urine examined in June, 1900, contained a decided trace of albumin and a very small quantity of pus or proliferated epithelial cells, with a few vesical epithelial cells, but no renal casts were found, nor was any blood found. The urine was acid and its specific gravity was 1013.

Several of the patients have had intestinal difficulties from which they have perfectly recovered. In one I thought malignant peritoneal growths might be developing, but the suspicious lumps which I felt in the abdomen were cleared away by laxatives and enemata and the patient is now quite well again. In another case I removed a large multilocular tumour with very friable walls, which had already burst in places before the abdomen was opened. The second ovary was also taken away I thought both ovaries were completely removed, but the patient, whose age was 36 years, had a slight white and red monthly discharge from the vagina until very recently. Two years after the operation this patient had an attack of severe dragging pain in the abdomen lasting a week, and she was afterwards confined to bed for four months, there being much difficulty in getting the bowels to act. The patient is now very well, and the periods have quite ceased.

In one case I thought that the tumour was malignant, but it was not examined microscopically. The patient has remained quite well. Several of the patients have borne children since their operations, one as early as 13 months afterwards. Two patients have married after single ovariotomy, and two after double ovariotomy. The latter appear to be quite happy. (One of the patients married, after double ovariotomy, in July, 1899, at the age of 25 years. She was quite well till Christmas when, after nursing her husband through a serious illness of some months' duration, she suffered from bearing-down pains with a vaginal discharge, and became very thin. I have not seen her since then.) In the whole series I have no knowledge of any case of hernia, but I have not examined all the patients.

Seven cases which are not quite satisfactory.—Of the cases in which there were no adhesions and in which the results were not quite satisfactory one patient was operated on when she was four months pregnant. The operation was quite a simple one, the tumour being of oval shape and about five inches in its longest diameter. The patient had no trouble after delivery at term, but she took little care of herself. Although advised to wear a belt she did not do so. She has now very lax abdominal walls, with wide separation of the recti muscles, but there is no hernia of the scar. The condition might have arisen without the operation having been performed, and was due to her neglect of obvious precautions. Of course, the tumour described did not cause any very great abdominal distension at the fourth month of pregnancy. (This patient died from acute pneumonia on April 9th, 1900. Obviously the condition of the abdominal walls must have diminished her chances of recovery from an acute lung disease.)

The second case was that of a woman, aged 50 years, who had borne 10 children. She complained much of debility and of an occasional dragging pain in the side. She also had a "pendulous belly," for which she had not worn any support. (When last I examined these cases, December, 1900, I could not find anything abnormal in either of them beyond the laxity of the abdominal walls.)

The third patient was 38 years of age. She said that she was in very good health but that she suffered from occasional soreness in the left side. I have not seen her recently.

In these three cases the unsatisfactory conditions might have arisen if the patients had never developed tumours requiring operations. Nor were the conditions very serious in four of the seven cases in which, after operations complicated by adhesions, the results were not altogether satisfactory. In one of these cases I removed a small tumour deeply embedded in the right broad ligament The patient was 37 years of age and had complained of pain and weakness in the back for 16 years before the operation. Now her only trouble is that her back is not strong. Everything else is satisfactory.

Another case was that of a woman, 43 years of age, from whom I removed an ovarian tumour deeply embedded in the right broad ligament and so thick-walled and red in colour that I mistook it for a fibroid uterine growth. Even after the abdomen was opened the tumour seemed to be a part of the uterus, but an exploring needle showed that it was cystic, and when the fluid contents were drawn off the relations of the parts were easily defined. The attachments were so extensive and the tumour was so friable that it was impossible to be certain that I had removed the whole of the new growth. The left ovary, which was also cystic and deeply buried in the broad ligament, was removed. This patient has complained much of pelvic and abdominal pains, but she can get about freely. She is very fat but not flabby, and she has all the appearance of being in robust health.

Another patient, aged 23 years, at the date of operation in January, 1896, had two ovarian tumours, each of about the size of a big cocoanut That of the left ovary, which had a very long pedicle, was situated in the right loin, no part of it being on its own side of the middle line of the body. The pedicle had become twisted, and the tumour was firmly adherent in the situation described. The tumour of the right ovary was in the right side of the lower abdomen, below and rather to the inner side of the left one. It was firmly adherent to the other and slightly adherent to neighbouring structures. Both tumours were removed. Since the operation the patient has been without any obvious signs of ill-health. She is stout and full-blooded, but she has complained a great deal of pain in the back and sensations of creeping in the head which are very distressing. The abdomen is soft and natural in every way to palpation, but the bowels are very constipated. The case seems to be one of severe neurotic symptoms due to the artificial change of life; and probably a gradual improvement will take place. I may add that the patient's medical attendant wrote recently that she had enjoyed excellent health since the operation. She is now at work.

In another case the patient, a married woman, aged 34 years, suffered from chronic inflammation of the ovaries accompanied by increasingly painful menstruation for seven years. She was under my observation for two years, and had been confined to bed for considerable periods under medical observation with only temporary benefit. The presence of new growth was not suspected. Eventually I opened the abdomen and removed two small ovarian tumours which were deeply embedded in firm adhesions. This patient made a rapid recovery but her periods have not ceased. About 18 months after the operation they became somewhat painful, and there was tenderness in the left broad ligament on palpation. In this case the sexual appetite has been so increased as to be a source of great distress. When I operated I thought that I removed both ovaries completely, but it is not possible to be certain of this when many adhesions have been separated (Since the above was written this patient has had prolonged intervals between the periods, and probably the menopause will shortly be established With the exception of the nervous symptoms the general health is very good.)

The results cannot be described as very bad in any of these seven cases, although they are not so good as might be desired.

Three cases which are unsatisfactory.—In the three following cases the results so far have been decidedly unsatisfactory. In the first I removed a small, flat tumour of the right ovary from numerous very strong adhesions. The patient had felt big in the abdomen and had suffered from increasing backache and difficulty in walking for three years before the operation Since the operation she has had much trouble from constipation, weakness, and pain in the side aggravated by walking Her condition recently in these respects is better than it has been and I may add that the patient seems to consider her health much more satisfactory than I think it. (Since the above was written this patient has improved very much She says that she is in good health though she cannot walk very far She is able, however, to "do a great deal of walking about indoors, mounting the stairs, about 40, many times a day." The bowels give little trouble and aperients are not required so often or in such quantity as was necessary a year ago.)

The second unsatisfactory case was that of a woman who had suffered from attacks of pelvic inflammation for six years before I saw her. She had been in several hospitals. In one she had been put under an anæsthetic and plugs had been inserted every night for a time, but she got no benefit I removed a small cystoma of the left ovary which was firmly adherent deep in the pelvis The ovary and Fallopian tube on the right side were also fixed by strong adhesions and were removed with difficulty Possibly the appendages were not completely extirpated in this case. The patient continues to have discharges of blood from the uterus, sometimes as frequently as every fortnight She has had attacks of peritonitis occasionally, like those which occurred before I operated, and recently these attacks have been more frequent. (In June, 1900, this patient was better in many ways, but she still had attacks of pelvic pain, although these did not occur so frequently as they did a year earlier. There was a tender thickening of the tissues in Douglas's pouch. The patient looked much more healthy than she did when I saw her 18 months earlier. This patient and the patient in the previous case are certainly improving in the local conditions, probably on account of a gradual yielding of adhesions.)

The last living case to which I shall refer was that of a patient whose age was 42 years. She had first noticed the abdomen large three and a half years before I saw her. It grew rapidly, and then all the signs of a rupture of a cyst occurred—namely, sudden violent pain followed in three days by complete disappearance of the swelling. In a few months the abdomen was again large, and again the tumour ruptured. This happened a third time. Two months before the patient consulted me her abdomen was tapped and three and a half gallons of clear fluid were removed. At the operation I found considerable omental adhesions and the pedicle of the tumour was very broad. The second ovary was healthy. This patient made a smooth convalescence. The temperature in the vagina rose to 101° F. on the second evening and was normal within a week. I have not seen her since she left my care a month after the operation, but she writes that she is much better than she ever expected to be. She says that she cannot hold her arms up without a burning and aching in her side and that she has "a great weakness." She cannot eat solid food. If she does she "is sure to bring it up again." The patient, who was a widow, was, however, well enough to re-marry within two years of the operation.

Three cases which have died.—Of the three patients who are now dead one has been referred to already in the earlier part of this paper. I thought that the growth was malignant, but I explored the abdomen and removed a simple multilocular cyst The patient was subject to frequent severe attacks of asthma and was extremely emaciated and feeble. She had no asthmatic attack, however, whilst under my care, although convalescence was prolonged very much by the formation of a bedsore. Recovery was ultimately good. Two years and three months after the operation the patient died from bronchitis complicating an asthmatic attack, the illness being of only two days' duration.

In the second of these cases the patient died from malignant disease six months after the removal of a semi-solid ovarian tumour. There were some adhesions to the omentum, but no real difficulties were encountered in the operation or during convalescence. Both ovaries were removed. Within three months the patient suffered from severe and increasing constipation. By the kindness of Mr. F. M. Corner of Poplar I saw the patient about a fortnight before she died and she then had large masses of new growth in the upper part of the abdomen.

The third case in which death has occurred was also one of malignant disease. The patient was 35 years of age and I had no doubt that she had an ovarian tumour. This had been diagnosed in India, but the patient had come home with the idea that she might be pregnant, and Dr. F. H. Champneys kindly saw her with me and confirmed the diagnosis of ovarian cystic disease. When I opened the abdomen I exposed an ordinary cystoma of the right ovary with a fairly small base. There were no adhesions However, when I had tapped and extracted the cyst I found that there was a solid tumour attached to it by a narrow neck. This solid growth was of the size of a very large orange and of a somewhat flattened, oval shape. It was buried in the outer part of the broad ligament, and was pressed so tightly against the iliac vessels and the pelvic brim that I had considerable anxiety as to whether I should succeed in removing it and arresting hæmorrhage. I was able, however, to get away all the visible new growth more easily and completely than I expected, the broad ligament being secured in many pieces. On the left side there was a slightly smaller solid tumour buried in the broad ligament exactly like that on the right side. This was attached by a narrow neck to an apparently healthy ovary in precisely the same way as the solid tumour on the right side was attached to the base of the ovarian cyst on that side. That is to say, both the solid tumours were completely extra-peritoneal between the folds of the broad ligaments. On the left side the ovary was attached to the broad ligament in the usual way and the solid growth was attached to it between the folds of the broad ligament. On the right side the ovary was replaced by a cyst which was also attached to a solid growth by a narrow neck between the folds of the broad ligament. I also removed the left ovary and tumour. I have never seen any tumours which at all resembled these solid growths in their situation and connexions. Microscopically they consisted of an epithelial growth of a papillary type. I exhibited the tumours at the meeting of the Obstetrical Society of London on May 6th, 1896, and a note concerning them appeared in the Transactions of that Society for that year (p. 166). The patient made a good recovery and returned to India in excellent health a few months later, but I warned the medical man who had sent her to me that her future must be looked upon with great anxiety. Eighteen months after the operation the patient (having lost her husband very suddenly) was again in England, and she consulted me in May, 1897, when I found a return of the growth. The tumour seemed to be to some extent moveable, but it had very extensive attachments in the pelvis and to the uterus. I decided that it could not be removed. I expected to see the patient again in July; but on the 9th of that month I was informed that she had been placed by her brother, who is not a medical man, under the care of another surgeon, the physician who had sent her to me not having been consulted. The patient had been seen twice by her second surgeon with an interval of about a month. I was informed that he stated that the tumour was growing rapidly and that he asserted in the most positive manner that it was not malignant, but that it must be removed at once. Neither I nor the gentleman who sent the patient to me was consulted, and the facts stated in the Transactions of the Obstetrical Society of London must have been unknown to the surgeon under whose care the patient had been placed. He operated on July 7th, 1897, and I understand that the difficulties encountered were very much greater that he had anticipated. The patient died on the next day. The operator was a man of very large experience. The incident proves the soundness of the opinion which I put forward at the beginning of this paper—namely, that mistakes are to be expected in dealing with these cases, and that statistical papers are of no value unless this possibility is recognised and full details of all cases are given whether an operation is performed or not.

The study of these and other cases has impressed upon me very strongly the importance of an early recognition and removal of ovarian neoplasms. When a tumour is buried deeply in the broad ligament at the beginning of its growth it is only by the merest chance that its removal will become more easy as time passes. It is quite as likely that it will bury itself deeper, and in every case delay in operating exposes the patient to the onset of complications which may cause great difficulty and great danger, when the abdomen is opened or before an operation is arranged for.

I wish now chiefly to point out that when inflammatory conditions are set up around an ovarian growth the risk of trouble *after complete recovery from the operation* is very much greater than it is when there has been no inflammatory disturbance. All the patients whose cases I have traced in the series under consideration in which the operation was simple, are practically in good health with the exception of the one who died from asthma (and, of course, of the one who died from pneumonia since this paper was read); and those who are known to be in bad health now had all suffered from prolonged inflammatory attacks before being operated on. There can, I think, be no doubt that in a series of uncomplicated operations for simple ovarian tumours, the success ought to be very nearly, if not quite, complete and perfect, and therefore no opportunity should be allowed for the development of complications by delay in operating. If the possibility of the existence of a malignant element in the tumour be considered the urgent necessity for early operation is still more obvious. Nevertheless, cases are even now seen in which, although ovarian tumours are recognised, either the patient is advised to wait till serious symptoms arise before being operated on or the possibility of operative treatment is not suggested.

There are, of course, cases in which the patient, on account of bashfulness or timidity or simply because there has been no sign or symptom of mischief, does not consult a medical man until some complication forces her to do so. When, however, an ovarian tumour is diagnosed it should be an absolute rule to have the question of its removal discussed at once. I have occasionally told a patient that I did not anticipate any harm from a delay of a few weeks, but the circumstances are very few in which it is advisable to postpone the removal of an ovarian tumour beyond the time necessary to make proper arrangements for the performance of the operation; and the reason for delay should never be that the patient is quite well. There must, of course, be always some risk in performing even the simplest ovariotomy, but this risk is smaller than that of allowing the tumour to remain. Although I am now chiefly urging an early resort to operative treatment in the interest of those patients who recover from ovariotomy, because the dangers of after-trouble are so much less if the operation is uncomplicated, and although I had not intended to deal with any cases operated on beyond the period during which the 50 cases referred to in the title of my paper were under my care, yet my unpublished fatal cases show so forcibly the increased immediate danger of an ovariotomy when the operation is too long postponed that I am only following out one line of argument by shortly recording the fatal cases of ovariotomy that have occurred in my practice and which are not already published.

Fatal Cases not hitherto Published of Ovariotomy and of Operations undertaken when Ovarian Tumours were supposed to Exist.

In two of these cases the patients did not seek medical advice until forced to do so by their inability to go about their work any longer. The first was a case of a single woman, 53 years old, who had known for some years that she was growing very large in the abdomen, but she did not consult a medical man until 14 days before her operation, and she was admitted to the Samaritan Free Hospital as soon as this could be arranged for. I do not remember ever to have seen a patient look so ghastly as this one did. Her hair was dark; her face showed no blood anywhere; she could not breathe unless she was sitting absolutely upright in bed; and she maintained this posture day and night by supporting herself on her hands. Her face and neck and her shoulders had little but skin over the bones, and her enormous abdomen increased by contrast the appearance of her anæmia and emaciation. Her temperature varied between 98·4° and 100° F. Her pulse, which ranged from 130 to 140, was very feeble. She was too ill to answer questions, and as she had lived alone no satisfactory history of her case was obtained. The abdomen was immensely distended, had a glazed shining appearance over its whole surface, and was very tender. It evidently contained a cystic tumour which also distended the pelvis. Obviously the prognosis was very bad, but after a few days the abdomen seemed a little softer and I thought it right to operate. I opened the abdomen on Dec 30th, 1898, and found a large tumour with recent adhesions to all the surrounding parts. Layers of white lymph, from a quarter to half an inch thick, covered its upper surface and extended between the coils of small intestine, which were matted together in the upper part of the peritoneal cavity. I removed the tumour, which was a suppurating multilocular ovarian cystoma, and I secured a thick pedicle on the right side in several pieces. Much lymph was taken away and the abdomen was closed, a drainage-tube being left in Douglas's pouch. In the evening, after the operation, the patient expressed herself as very comfortable. She could lie down and breathe comparatively freely. Her temperature was 100·8° and her pulse was 136 In the night the bowels began to act and the patient collapsed and died rather suddenly between three and four o'clock on the next morning. After death it was found that the last six inches of the ileum were in a sloughing condition. It is quite possible, and I think likely, that a month before this operation was performed the patient had a very large ovarian tumour without inflammation, adhesion, or any complication, and that then an operation would have been fairly free from danger. Tapping the cyst would have been as certainly fatal as the operation which was performed.

In the second case the patient, who was 50 years of age, had suffered much pain and had known that her abdomen was very large for more than two years before she sought advice. I operated on March 17th, 1899. The right ovary consisted of a large suppurating tumour deeply embedded in the broad ligament and pressing the ribs firmly upwards. Its walls were so fragile that it was quite impossible to prevent the escape of its contents at the side of the tapping cannula. At the same time the walls were so thick and so little pliable that the cyst could not be drawn out partially until the adhesions behind were separated. I made a very long incision in the abdominal wall; but there were many strong adhesions high up in the peritoneal cavity, and fouling of the peritoneum by the pus from the tumour was unavoidable during the necessary manipulations. When the bulk of the cyst was removed from the abdominal cavity, a deep enucleation from the broad ligament was necessary. The uterus was so completely atrophied and was drawn up so high on the tumour that it was mistaken for the end of the Fallopian tube and was removed inadvertently. I noticed this at once, and the stump of the uterus was properly secured after tying the uterine arteries as in a case of hysterectomy. The left ovary consisted of a cystic tumour with a good pedicle quite free from the uterus. There were some slight adhesions, but this tumour was easily removed. I carefully cleansed the peritoneum and drained the pelvis by means of a glass tube. At first the patient seemed as if she would do well, but she died from septicæmia on the eighth day. Extensive purulent inflammation of the peritoneum was found after death; the intestines were much distended and seemed in places as if they had been about to give way. The septic mischief must have developed from the pus spilt at the operation, or possibly a fresh dose of the poison escaped through the intestinal walls. The original cause of suppuration in the tumour had probably come from some adherent bowel. There can be no doubt that if an operation had been performed on this patient at an earlier date she would have had a very good chance of doing well.

In the third case the patient was 44 years of age and her first trouble was a difficulty in passing urine two years before I operated. A catheter was required then and frequently afterwards, but the tumour did not seem to have been detected and the patient did not notice any swelling. Two weeks before admission to the Samaritan Free Hospital the patient was living in Croydon and was knocked down by a cab there. Mr. G. Wale of that town was called in and at once discovered a tumour. It extended from the pelvis as high as the umbilicus and dragged up the uterus so far that the tumour was much below the level of the os uteri. There was tenderness in the right groin after the accident, and the temperature was above normal, sometimes as high as 101° F. I operated on Oct. 10th, 1899, and removed a multilocular cystic tumour of the left ovary which filled the pelvis and was firmly held there by suction and by adhesions. On the right side there was a very much swollen ovary. The fimbriated extremity of the Fallopian tube was occluded and the tube itself was much distended. I removed the ovary and tube with great difficulty without opening the tube I could not find the vermiform appendix, but I suspected that it was buried in the adhesions from which I had removed the inflamed right tube and ovary. The parts removed seemed fairly clean, however, so I closed the abdomen, placing a drainage-tube in Douglas's pouch. This was removed after 24 hours, as the amount of fluid escaping through it was very slight and was quite sweet. Dr. Cuthbert Lockyer kindly examined the right Fallopian tube for me and got from it a pure culture of staphylococcus pyogenes aureus. For the first 10 days this patient seemed to do well, except that she was remarkably sleepless. On the second and third days her temperature rose to 103·2° and 102 6° respectively. It then gradually fell, and from the seventh day to the tenth the temperature was below 100° in the vagina. Up to the tenth day the condition of the abdomen seemed perfectly satisfactory, the bowels having been freely moved by enema on several occasions. The only difficulty was the persistent sleeplessness, for which it was necessary to give opiates. These secured the needed rest, but on the eleventh day the temperature again rose, the respiration became laboured, and there was slight expectoration. The weather was very cold and foggy, and I attributed the adverse symptoms to an inflammatory condition of the lungs. On the thirteenth day there was a suspicion of tenderness and fulness in the right groin; her temperature rose to 103 6°, and the patient died on the following day. At the post-mortem examination made by Dr. William C. Bosanquet it was found that the upper part of the abdomen was shut off from the lower part by adhesions. Below there was considerable peritonitis, with pockets of purulent lymph amongst the coils of intestine and along the ascending colon. The lungs were intensely congested and of a dark purple colour, the lower lobes being in a condition of nearly solid œdema. The heart was very soft and flabby, but the valves were normal and there was no naked-eye evidence of fatty change. The vermiform appendix was bound down by old adhesions but was itself reported as healthy

Probably in this case there was an inflammation in the situation from which I removed the right tube and ovary, and this was at first shut off by adhesions; the sleeplessness was, I presume, a result of absorption of poison; the enforced quiescence induced by opiates led to congestion of the lungs, and the peritonitis then made rapid progress. I think it is quite possible that until the lungs became congested there was no pus in the abdomen. The fact that there was no distinct sign of mischief in the abdomen for ten days is very unusual in my experience of ovariotomy, but an insidious onset of septic peritonitis in cases of inflammation of the vermiform appendix is not very unusual, and it is fairly certain either that I had not removed all the infected tissues or that fresh infection occurred later. During the operation I thought of making a small opening in the groin and passing a gauze drain down to the position from which I had removed the right ovary. Probably this would have saved the patient's life, but unfortunately I decided that I had removed all the infected parts. It is certain that if this patient had been operated upon before she was knocked down by the cab the conditions would have been much more favourable, but up to that time the presence of a tumour seems to have been overlooked.

In the case of a patient, aged 60 years, I explored the abdomen on Jan. 13th, 1897, and found that there were two malignant ovarian tumours with secondary deposits in the omentum. I closed the abdomen at once and sewed up the wound, without attempting to remove the tumours. On the next afternoon, at 3 30 o'clock, every sign was favourable, and the patient said that she was very comfortable. At about half past four, after a quiet sleep, she woke up in a state of extreme restlessness, with a quick pulse and much difficulty of breathing. In my absence Mr. Alban Doran and Mr. Corrie Keep kindly did all they could for the patient, but she did not rally and she died somewhat suddenly at 8 20 P.M. At the post-mortem examination it was found that the tumours were attached to and invaded the walls of the intestine in several places, there being a mass of the size of a bantam's egg in the cæcum. The omentum also contained much malignant deposit. Dr. W. H. Allchin made the post-mortem examination and reported that the heart was "much dilated, soft, and flabby, and exhibited fatty invasion to an extreme degree, the left ventricular wall at places being almost replaced by fat."

There is little doubt that the cardiac condition was the cause of death. It is not possible to ascertain exactly the relations of an abdominal tumour in such a case as this without opening the peritoneal cavity. Probably no good could have been done in this case by operation at any time, unless perhaps at a very early stage, but the fatal issue would not have been likely to occur if the exploration had been done earlier. I have only had one other fatal case at all comparable to this one, and that also was a case of advanced malignant disease[4]

In the following case I diagnosed an inflamed ovarian tumour. The patient, who was 30 years of age, had been married 11 years and had borne six children. She had a soft, indefinite swelling to the left of the pelvis, pushing the uterus over to the right and rising nearly to the level of the umbilicus. She had been delivered of a dead child seven months before I saw her, and she dated her illness from that confinement. Throughout the 10 days during which the patient was in hospital before the operation there was only a very slight rise of temperature, 99·6° F. being the highest recorded. I opened the abdomen on June 25th, 1897, and found the contents of the pelvis so matted together that I had great difficulty in making out the relations of the viscera. After separating much omentum and opening many cavities containing fluid I succeeded in removing both ovaries and Fallopian tubes which were very much inflamed. The pelvis was drained by a glass tube and by iodoform gauze. Although there was a high temperature early in this case the abdominal condition progressed favourably and the abdomen remained soft and flat. On the fourth day the left parotid gland swelled. It was incised on the fifth day and discharged unhealthy pus until the patient died on the tenth day. After death numerous abscesses were found in the lungs and the left parotid gland was in a sloughy c[illegible]ition. The peritoneum showed neither lymph nor pus formation except in the pelvis, the site of the operation being shut off from the rest of the peritoneal cavity by adhesions. So far as I am able to speak definitely this was not a case of ovariotomy for new growth, but the operation was begun on the assumption that a tumour existed. The disease appeared to be an intense septic inflammation beginning in the Fallopian tubes and the infection was not completely removed.

Another fatal case is recorded here because I thought before the post-mortem examination that the mischief probably began in the ovary. The patient was a single woman, 34 years of age, who was sent to see me about the middle of October, 1899, by Mr. Isaac Coalbank of Teddington. She had complained of increasing constipation for over a year, but she did not consult Mr. Coalbank until, by the advice of a friend, she had taken some liver pills and so had made herself very much worse. I found a very hard growth in the right loin about the level of the umbilicus and an equally hard mass pressing low down in the pelvis on the right side. There was considerable intestinal distension, which made it impossible for me to estimate the size of these masses and whether they were connected or separate. The intestinal distension increased, and I admitted the patient into the hospital on Oct. 31st A distended coil of intestine was then very obvious in the neighbourhood of the cæcum, and in spite of many lumps of fæces being removed from the lower bowel by enemata, this coil continued to increase in size rapidly until it was very tense and painful and stood out prominently from the rest of the abdomen, which was also distended but not to any great degree. I thought that the mischief depended on an ovarian new growth, and the existence of secondary deposits seemed probable. There was no prospect of my being able to do more than relieve the patient by the formation of an intestinal fistula, but surgical interference seemed necessary on account of the painful tension in the distended gut. On opening the abdomen in the right groin I found the omentum studded all over with new growth, and there were large masses in the pelvis. I opened the distended gut, which was the cæcum, and made a fistula. The obstruction was, however, only partially relieved; much fæces but very little flatus escaped; the general abdominal fulness did not go down, and the patient died early on the next morning. By post-mortem examination it was found that the malignant disease was much more extensive than I had thought. It appeared to have begun in the greater curvature of the stomach, where there was a considerable mass which had induced a malignant ulcer of the mucous membrane. The ovaries were normal, but large masses of secondary disease occupied the pelvis and were attached to the ovaries. The intestines and the peritoneum generally were affected at numerous points. It is remarkable that neither sickness nor vomiting was a prominent symptom in this case.

In one case there is room for doubt as to whether I removed an ovarian new growth or an abscess of the ovary. I was asked to see the patient in July, 1897, by Dr. J. W. Walker of Peckham Rye, and I diagnosed an inflamed left ovary and Fallopian tube At this time it was not possible to say definitely that there was an enlargement of the ovary. The patient's general condition was good and she had recently come home from India where she had been a semi-invalid for many months. As complete rest had not been taken, except in a very intermittent way, I suggested that the patient should lie on her back for a couple of months and be treated by counter-irritants and warm douches. The inflammation diminished and all went well for six weeks. The patient was then suddenly seized with acute symptoms. I was out of town and when I returned a fortnight later I found that there was a large mass in the left side of the pelvis. It was acutely inflamed and the patient had much fever of a hectic type. Without further delay, on Sept. 29th, I removed the left ovary, which was of the size of a large cocoanut and contained one large abscess cavity. The mass was very firmly adherent to several coils of intestine above it. For a few hours the patient seemed better, but she was already in a septic condition. Towards night she began to rave, and she died very early on the following morning. If I had operated on this patient soon after I first saw her I should probably have performed an easy and safe operation. I think the case was one of acute infection of a chronically inflamed ovary.

I must mention one other case to complete the list of my fatal cases of ovariotomy and of those other fatal cases in which an ovarian tumour was or might have been diagnosed. I removed this patient's ovaries for chronic pain due, I believe, to the presence of a small fibroid tumour pressing on the left Fallopian tube. There was a small cyst of the right ovary which I had not diagnosed but which makes it necessary for me to mention the case here. The patient died from hæmorrhage 12 hours after the operation. The case does not invalidate my argument that ovarian tumours should be operated on early. In cases of death from hæmorrhage after ovariotomy I should not like to say that the surgeon has always been to blame, but there can be no doubt that in most cases a somewhat different disposition of the ligatures, or a little more force used in tying them, would have saved the patients' lives. I have been responsible for the treatment of secondary hæmorrhage twice in my own practice and once in that of a colleague during his absence, and I have had the good fortune to save two of these patients. Both are ignorant of the danger they passed through.

In a fourth case, not one of ovariotomy, I arrested secondary hæmorrhage and saved the patient's life for a time, but the details of the case have no bearing on this paper and will be published elsewhere. There are a few causes of death after ovariotomy which, like hæmorrhage, may be described as accidental and which are mostly preventable. If such causes of death be set aside, the cases which I have recorded in this paper clearly prove that delay in operating is the chief cause of fatal results in ovariotomy and also of unsatisfactory conditions arising in patients who recover from this operation. I would urge, therefore, that it is the duty of medical men whenever these tumours are diagnosed to advise their removal without any unavoidable delay. In conditions such as the presence of a uterine fibroid tumour in which there may be a reasonable prospect that the patient will not require an operation at all, there is often room for a difference of opinion as to whether an operation should be performed, and there are also cases of ovarian tumour in which an operation appears so formidable that it may not be considered wise to undertake it; but an ovarian tumour is sure to give trouble sooner or later, and it should therefore be removed as soon as diagnosed if such treatment seems at all practicable. This is the only way in which patients can obtain the full benefit of the well-known advances which have been made in abdominal surgery.

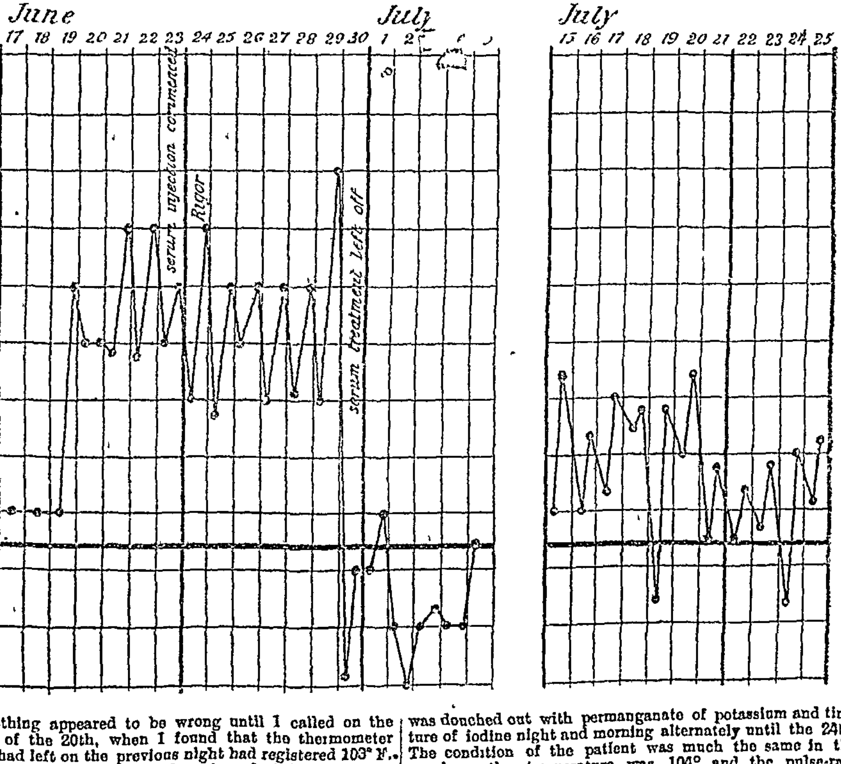
ADULTERATED GOLDEN SYRUP.—At the Newport County Petty Sessions held on Nov. 24th, a grocer of Pontymister, Monmouthshire, was summoned at the instance of the Monmouthshire County Council for selling golden syrup adulterated with glucose. Evidence showed that the "syrup" consisted of 20 per cent. of pure sucrose and 80 per cent. of glucose. The defendant was fined £20 and the costs of the court.

A CASE OF PUERPERAL SEPTICÆMIA TREATED BY ANTI-STREPTOCOCCIC SERUM,

COMPLICATED BY PULMONARY EMBOLISM, PERIMETRITIS, AND AXILLARY ABSCESS; RECOVERY.

BY B. T. READ, L.R.C.P. LOND., M.R.C.S. ENG.



THIS patient, a primipara, was confined on June 16th, 1900. The presentation was that of the first vertex position and the labour was not protracted. The placenta and membranes were complete and the perineum to all intents and purposes was intact. These points I wish to emphasise before going any further, as well as the fact that I did not examine the patient *per vaginam* to ascertain if there was any internal laceration, although the skin was untorn. Before leaving the room I told the patient, in her mother's presence, to keep her bed for ten days, not to sit up, and to use the bed pan which I had lent her. Nothing appeared to be wrong until I called on the morning of the 20th, when I found that the thermometer which I had left on the previous night had registered 103° F. There was, moreover, a nasty odour from foul discharge perceptible on going into the room. The patient had a flushed face and a septic smell about her breath, and there were slight dyspnœa, cough, headache, nausea, and a pulse-rate of 100. There were a few moist sounds to be heard over the base of the left lung; she had had a cough or "cold" before her labour commenced. On examination I found that the perineum was torn through to a fraction of an inch from the anal orifice. The accompanying chart shows the temperature throughout. The patient on cross-examination gave a history of having left her bed on the morning of the 19th and of having used the night-stool because she did not care to use the bed-pan. Shortly afterwards she had felt cold, but there had been no rigor. As her bowels had been well opened I gave her half an ounce of Warburg's tincture and repeated it after two hours and prescribed an expectorant mixture. The vagina was douched out night and morning with tincture of iodine and permanganate of potassium alternately and the wound was dressed with creolin powder and gauze, &c. I decided to keep the wound as aseptic as I could and to have the operation of restoration of the perineum done later. On the morning of the 21st the dyspnœa had increased, the face was flushed, the countenance showed anxiety, and there were headache and nausea. The temperature was 101·8°, the pulse was 120, and the respirations were 32. On auscultation there was a murmur over the pulmonary artery at the cardiac base and another distinct murmur which was systolic in rhythm at the apex. At times the patient panted and moved her head from side to side in urgent distress. For several days she had these urgent oppressive attacks, but they passed off. The evening temperature was 104° and the general condition of the patient was much the same. I douched out the uterus with permanganate of potassium. The morning visit of the 22nd showed no change; the discharge continued to be offensive, the temperature was 101·8°, the pulse was 120, and the respirations were 36. The uterus was douched out with permanganate of potassium and tincture of iodine night and morning alternately until the 24th. The condition of the patient was much the same in the evening; the temperature was 104° and the pulse-rate remained the same. As this condition was a serious one I decided to telegraph for anti-streptococcic serum on the next morning (the 23rd). The patient had undoubtedly contracted septicæmia and as far as I could judge there were embolic deposits on the pulmonary and mitral valves, for in no other way could I account for the signs and symptoms which I had observed in her. It appeared to me that the emboli must be minute, and I was afraid that fresh deposits would take place. On the morning of the 23rd the anxiety, the dyspnœa, the flushing of the face, and the foul discharge continued, together with headache and nausea; the pulse was 130, the respirations were 36, and the temperature was 102°. I injected 10 cubic centimetres of the serum at

5 P.M., taking the usual antiseptic precautions. Ten minutes after the injection the patient complained of her head whirling round and of a feeling of sinking through the bed. This lasted for about half an hour and then she felt better; the headache and nausea had entirely disappeared and they did not recur until 12 hours had elapsed On the following day I injected 10 cubic centimetres of serum at 7 A.M., 14 hours after the first injection. The aspect of the patient was much the same, the pulse was 140, the respirations were 40, and the temperature was 103°; 10 cubic centimetres of serum were injected at 7 P.M., and the injection was followed by the same sensations, with about the same interval as before and with the subsidence of the headache and the nausea. This happened each time after the injection of serum up to June 29th, when, unfortunately, I was disappointed in the serum not arriving as I had run short of it. On calling to see the patient on the 25th I learnt from her mother, who had been present at the time, that she had had a shivering fit on the previous night, when she shook from head to foot and her teeth chattered. The thermometer which I always left showed 104°. The temperature was 100·8° at 7 A.M., the respirations were 42, and the pulse was 133. I could find nothing to have caused this rigor. There were no additional signs in her chest, the murmurs remaining the same, and the abdominal symptoms of perimetritis were much the same. There was enteritis. The discharge had lost some of its fœtor. I now had the vagina douched out night and morning only. The noticeable good sign, if I may say so, was the descent of the temperature to 100·6° in the morning. The pulse-rate continued to be fast, but, as I observed afterwards, her pulse could not be relied upon alone as she was such a nervous woman and her ordinary pulse varied from 92 to 108. From the 26th to the 28th the patient went on as satisfactorily as could be expected until the serum supply failed me on the night of the 28th, when I used the last 10 cubic centimetres about 7 P.M and there remained none for the morning of the 29th. On calling to see the patient on that morning the mother informed me that her daughter became so ill in the previous night that she thought that she was going to die, unconsciousness and delirium setting in. On going upstairs to see the patient I found her suffering from a bad headache and from nausea which came on when the serum injection was due and which continued throughout the day until I injected the serum again at 6 P.M. soon after its arrival. The same result happened, the nausea and the headache disappearing at the same time. The temperature registered 105° at 9 P.M. and suddenly fell to 96·4° on the morning of the 30th when I stopped the serum treatment. Her pulse-rate had now decreased to 115 and the respirations to 30. The septic discharge had entirely disappeared. On vaginal examination there was still a great deal of tenderness and swelling both in Douglas's pouch and in the left side of the pelvis. About this time both the pulmonary murmur at the base of the heart and the systolic bruit at the apex had almost entirely disappeared. From the night of the 30th to that of July 6th the patient's temperature kept below 99° and her pulse varied from 96 to 106. Then a change set in, her temperature rising to 101°. From the 7th to the 14th her temperature did not show any variation, remaining at 99° in the morning and 102° at night. During this period an abscess formed in the left axilla. There had been a tender nodule on the outer edge of the left breast without any mammary abscess. It was now apparent that the patient had drifted into a state of chronic pyæmia Throughout this time she was taking nine ounces of brandy in 24 hours and champagne and fluid nourishment. I had her temperature taken every four hours from 9 P.M. on the 15th to 9 P.M. on the 24th. The abscess was opened on the 18th. The patient made a steady but slow recovery and her temperature remained normal on August 15th and I left off attending her on the 18th

As regards the treatment in this case the following details may be given. During the early stage of the acute septicæmia the patient had half an ounce of Warburg's tincture on an empty stomach after the bowels had been relieved and this was repeated in two hours. That had not the slightest effect on her temperature. I followed this up with six ounces of brandy in 24 hours and two grains of hydrochlorate of quinine in pill form together with beef-tea and milk. She had 25 grains of trional on June 30th for insomnia. I was obliged to give her five grains of calomel on July 7th. It was not till July 12th that I had to give her half a grain of opium three times a day, and to have her left hypogastric region painted with equal parts of liniment of iodine and tincture of iodine. When fresh symptoms of enteritis became more marked on July 14th I gave her opium pills which may have been the means of helping the absorption of all inflammatory products.

I take it that the serum treatment is conclusively proved to be good and trustworthy for the following reasons. The patient in this case had headache and nausea which entirely disappeared when the serum was used. If I was only a few minutes after my time in injecting the serum the head became worse and the feeling of nausea recurred. Then, again, as to the bad symptoms that set in at the time during which the patient was without the serum injection on June 29th from 7 A.M. to 6 P.M. (when the treatment was resumed), what was the result of this perseverance on that evening? It caused the sudden fall of the temperature from 105° to 96·4° on the following morning The pulse had slowed down to 115, the respirations to 30—instead of 42—and the foul discharge had disappeared. A correspondent in THE LANCET[1] has recently cast a slur on the usefulness of the serum treatment and I should like to know whether these notes of mine will convince him. I for my part consider that I would have lost my patient without the serum treatment. I have never heard or read of another case of a lying-in woman, in or out of a hospital, getting out of bed on the third day for any purpose, for defecation or otherwise, and recovering from such a severe attack of puerperal septicæmia complicated by pulmonary embolism.

Odiham, Hants.

MERCUROL AS AN ANTISEPTIC IN DISEASES OF THE NOSE AND EAR.

BY R. LAKE, F.R.C.S.ENG.,
SURGEON TO THE ROYAL EAR HOSPITAL AND TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, ETC.

MERCUROL, for the information of those who are not acquainted with it, is a brownish-white powder, soluble in water but insoluble in alcohol. It is a compound of mercury with nucleinic acid and contains about 10 per cent. of mercury; therefore, a 5 per cent. solution of mercurol contains one-half per cent. of mercury and this in a form which is non-corrosive and non-irritant. It is at the same time an organic compound and does not precipitate albumin; the general idea which mercurol gives being that at one and the same time it is an antiseptic in the usually understood sense of the word and will act indirectly on the protoplasm of the nuclei, more especially of the large white blood cells, as the phagocytes, and thereby enable them the more readily to overcome micro-organisms and destroy them in larger quantities. One disadvantage of solutions of mercurol is that one cannot make it up in large quantities, a week being probably the longest time in which it can be kept with safety; this, however, is equally true with that most useful antiseptic, formalin, but there is no doubt that in order to obtain the most efficient action of mercurol it requires to be employed, like chlorine, freshly made.

I have not kept regular statistical accounts of all the cases of chronic suppurative otitis which I have treated with mercurol; and even if I had the probability of mercurol being found largely superior to other antiseptics in this disease is very problematical, chiefly on account of the mechanical obstructions to the antiseptic reaching the parts affected. In acute suppurative otitis, however. the conditions are very different. I have used it in three cases immediately after incising the membrana tympani. It should, of course, be used to disinfect the canal previously to the operation where it is to be used afterwards as the antiseptic. The three cases were all cured within ten days, the most rapid cure being four days.

CASE 1.—The patient, aged 27 years, came to the Royal Ear Hospital suffering from keratosis obturans. This required a long and tedious process of removal, which, however, when effected, as it was somewhat suddenly, set up an acute otitis media. The membrane became red and bulging and there was at the same time a small anterior perforation through which pus extruded. An incision was made over the swelling and the middle ear was irrigated with 2½ per cent. of mercurol. This solution was used to irrigate the ear three times daily and a complete recovery was obtained in ten days.

---

[1] "Puerperal Sepsis," by R. P. Ranken Lyle, M.D. Dub., THE LANCET, Sept. 29th, 1900, p. 925.

It must be said here that in neither of the acute cases was there left any impairment of the hearing. As a means of treating acute suppurative otitis media (after perforation has occurred) I can very highly recommend the injection into the cavity of the middle ear by means of the Eustachian canal of a small quantity of a 5 per cent. solution of mercurol. By such treatment a more rapid and effective cure is usually gained than by any other, its only disadvantage being that it almost of necessity should be left to the specialist to carry out. That one does obtain extremely good results from mercurol in chronic suppurative otitis media cannot be denied, but at the same time for my own part I would not, as before stated, consider this drug to be to any extent superior to, say, perchloride of mercury or carbolic acid. The following may be taken as an example of the treatment of chronic otitis media.

CASE 2.—A woman, aged 31 years, had suffered from discharge from both ears since, at the age of six years, she had had scarlet fever. The discharge was very offensive. On the right side there was a perforation in the posterior superior quadrant and one also in the anterior inferior, while on the left side there was a sinus leading into the antrum with a small posterior perforation on a level with the tip of the handle. 5 per cent. of mercurol was ordered three times daily as an injection. At the end of six weeks the discharge on the left side had entirely ceased and was reduced to an inodorous, clear, watery discharge on the right side. The mercurol solution was then reduced to 2½ per cent. and the patient was seen again in three weeks' time, when the discharge had entirely ceased on the right side.

As an example of the use of mercurol in diffuse inflammation of the external meatus the following case may be mentioned.

CASE 3.—A man, apparently of gouty habit, came to me complaining of discharge from one ear. The meatus was entirely occluded by diffuse swelling; the discharge was thin and very purulent—that is to say, there was acute gouty affection (eczema) of the ear. He was given mercurol in a 5 per cent. solution and immediately obtained the greatest relief from the irritation. The swelling in the canal disappeared extremely rapidly, and, what is much more important, the mercurol seemed in this instance to have effectually prevented contraction.

The following is an instance of the use of mercurol in chronic suppuration of the maxillary antrum.

CASE 4.—The patient was a man, aged 38 years, who was under the care of Mr. E. T. M. Tunnicliffe who brought him to me with the following history. The patient had had a nasal discharge for six months from the left side which had all along been offensive at times. On pressure within the nostril offensive pus could be evacuated by the patient. On examination of the left nose a large projection was seen below the inferior turbinated bone. This was soft and elastic, giving a feeling of a dense wall cyst, from which pus could be made to exude at the posterior part if firm pressure were applied. This was incised and some drachms of extremely offensive pus were evacuated, and on examination the abscess cavity was found to be continuous with the maxillary sinus, the lower part of the internal bony wall of the antrum being entirely absorbed. The cavity was irrigated with 5 per cent. of mercurol and was packed with iodoform gauze. In three weeks' time there was practically no discharge and absolutely no smell; the latter, I was informed, had never reappeared after the first washing with mercurol. The percentage of mercurol was now reduced to 2½, which was kept up as a matter of precaution for another three weeks, when the opening was allowed to close, perfect cure having been obtained.

CASE 5.—The patient, a female, had suffered from chronic suppuration of the maxillary antrum for at least 18 months. The antrum was opened through the alveolus on the right side at the side of the first molar which had been removed some time previously. There was a fair amount of pus in the antrum and the lining membrane was much thickened as detected by the probe. Irrigation with mercurol (1 per cent.) was carried out regularly twice daily with the result that there was a complete cure in six weeks.

I have used mercurol (2 per cent.) twice after operations, one being a double ossiculectomy and the other an operation for opening the frontal sinus. The wounds in both cases remained in an absolutely satisfactory and aseptic condition, though one would frequently find it necessary to change from so bland and unirritating an antiseptic to one having the strongly caustic properties of 5 per cent. of carbolic acid, especially where much ulceration remains, the tendency of which to secrete it is frequently desirable to overcome. I have also irrigated the frontal sinus with it *viâ* the infundibulum with satisfactory results, but as these cases have been amongst hospital patients and I have been unable to see them sufficiently often I cannot attribute a cure to mercurol in this respect, though the general impression I derived was that had I been able to use it sufficiently often, say daily, it would have given better results.

With regard to chronic suppuration of the middle ear I have only quoted one case. From the small number of cases in which the drug was systematically used the general results may be apparently slightly above the average obtained by other antiseptics. But, as before remarked, it is the anatomical and mechanical obstruction to the penetration of any particular remedy to the seat of disease that renders this ailment so intractable. So to claim for mercurol any peculiar and specific action in this disease would be, in my opinion, absurd. My general impression is that mercurol is the least irritating efficient antiseptic with which I am acquainted, being possessed of properties which commend it highly, especially as a lotion for the irrigation of cavities such as the maxillary sinus.

Harley-street, W.

A CASE OF MORPHIA-POISONING TREATED BY ATROPINE.

BY EDWARD GROUND, M.D. CANTAB.

As there is a certain difference of opinion among authorities on toxicology as to the value of atropine in morphia-poisoning I think the following case may possibly be of interest to readers of THE LANCET.

A few weeks ago, at about 2 P.M., I was summoned to see a man, aged 61 years. His wife told me that he had been in bed for two or three days suffering from an attack of influenza and that shortly before she sent for me he had been seized with faintness which alarmed her very much. I found him in bed, looking rather sleepy (he had had a good dinner); his face was flushed, his pulse was quick (about 100), and his pupils were contracted. On being questioned he strenuously denied having taken any opiate and his wife who had been with him while he was having his dinner said she was quite sure that he could not have taken any without her knowledge. I was sent for again in a hurry at 5 P.M., an empty one-ounce bottle, labeled "Liq morph. hydrochlor.," having been found in his room. When I arrived (at 5 30) I found him very drowsy and looking very pale, sweating profusely, and with very contracted pupils. He then admitted that he had taken one ounce of solution of hydrochlorate of morphia in his brandy-and-soda at dinner-time, under the impression that he was taking two grains of morphia. After a little difficulty I persuaded him to take an emetic, but he only brought up a little tea which he had taken shortly before. I then gave him a hypodermic injection of a thirty-third of a grain of sulphate of atropia and three grains of permanganate of potash in pill every three hours, with the idea of oxidising any unabsorbed morphia that might remain in the intestinal canal. At 7 P.M., although he could only be roused with difficulty, his general condition had undergone a marked improvement. The pallor had given place to a distinct flushing of the face, the profuse sweating had stopped and the skin was dry, the pupils were less contracted, and the pulse had improved in tone and in volume. The injection was repeated then, and again at 9 30 P.M., when he was quite insensible but otherwise about the same. At 11 P.M. another injection of atropine was given, with one-thirtieth of a grain of sulphate of strychnia, as his pulse was inclined to fail. He remained quite insensible, but his breathing never became stertorous, until about 12.30 A.M., when, after vigorous shaking, he began slightly to raise his eyelids and to show signs of returning consciousness. At 4.30 A.M., after constant shakings, moving of his arms and legs, with artificial respiration, he became conscious and gradually recovered.

A great many cases of opium- and morphia-poisoning successfully treated with atropine have been reported in which the dose of poison was very much larger than in this case. A case has been described by Dr. D. T. Playfair,[1] in which a woman, aged 37 years, took 30 grains of acetate of morphia, a fact which was not discovered until three hours afterwards. Four injections of atropine, each of one-fortieth of a grain, were given, but the recovery of the patient was attributed to the prolonged use of oxygen gas with artificial respiration, all natural respiratory movements having ceased for several hours. Mr. Percy Pope[2] records a case of recovery in a girl, aged 19 years, after a hypodermic injection of 12 grains of morphia. The treatment consisted in the administration of four grains of atropine in doses of one-twentieth of a grain at short intervals during 12 hours and in artificial respiration, strong coffee, and attempts to rouse the patient. Cruse describes the case of an infant, one week old, who was accidentally poisoned by a grain of morphine. The comatose condition that resulted remained unaffected by various treatments for several hours until a quarter of a grain of atropine was administered and the dose repeated after an interval of half an hour. Recovery was complete in 38 hours and no unpleasant symptoms attended the administration of such large doses of atropine. From the marked improvement in my patient I should be inclined to regard atropine as a valuable remedy in opium-poisoning; but there appears to be one difficulty, and that is to know when the limit of safety has been reached with regard to the amount of atropine to be used. The action of morphia and atropine is not exactly antagonistic, the former acting centrally and the latter peripherally. According to Dr. J. Dixon Mann, "Morphia slows the heart's action by excitation of the vagus at its origin in the brain; atropine quickens the heart by paralysing the terminations of the vagi and the inhibitory ganglia in the heart. ...... Opium acting centrally contracts the pupils; atropine paralyses the terminals of the oculo-motor nerves. Opium causes sweating by stimulating the central nerve apparatus concerned; atropine arrests it by paralysing the nerve terminals in the sweat glands." Ultimately, however, the effects of the two poisons become mutual, both paralysing the motor and sensory nerves, atropine especially paralysing the heart and opium the respiratory apparatus. Some caution, therefore, is required in using the antidote. Dr. A. P. Luff recommends that it be given in frequently repeated doses until half a grain has been given, and this should provide a fair margin of safety. My patient took about four and one-third grains of morphia which is not a very large dose, and one-eighth of a grain of atropine was given as an antidote, which, I believe, contributed largely to his recovery. There is one point that is rather impressed on the mind in considering this question and that is that however large the dose of opium or morphia may be there need be no despair, with the help of atropine, oxygen, and artificial respiration, of rescuing from death the person poisoned even after the poison has become thoroughly absorbed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF ARSENICAL BEER POISONING.

By J. HAROLD BAILEY, M.B. VICT.

ON Oct. 9th, 1900, I was called in to attend a married woman, aged 41 years, residing in Pendleton, she having slipped and sprained her left ankle. Rest and the application of lead and opium lotion to the injured joint were prescribed. The swelling around the joint subsided and the pain, which was severe, abated somewhat, but at the end of a week the patient began to complain of pains and tingling in the left foot, and she was unable to stand upright and was obliged to remain altogether in bed. Cramps in the calves of both legs were next complained of, and the feet and legs became exceedingly painful to pressure on any part of them; she also complained of the weight of the bed-clothes and of being unable to sleep at night owing to the intensity of the pains. After another week the patient noticed that her hands were becoming affected, saying that they felt numb to the touch, though painful sensations like "pins and needles" were present. She could not use her hands, moving the fingers with difficulty. Her appetite began to fail, the tongue became slightly coated, and vomiting of yellowish bile occasionally occurred. Before being confined to bed the patient had been accustomed to have beer for supper and she admitted having taken a glass or two since. Hearing late on Nov. 20th that Dr. E. S. Reynolds had detected arsenic in beer in Manchester I called at the patient's house on the morning of Nov. 21st and sent out for a jug of the beer which she was in the habit of drinking; this was obtained from the shop whence she had been getting her beer, and on its being analysed by Mr. William Kirkby, F.L.S., of Owens College, it was found to contain 0·14 grain per gallon of As_4O_6. A sample of urine from the patient failed to show the presence of arsenic, though in the case of another patient of mine who had drunk the same beer and was suffering from symptoms of arsenical poisoning the urine showed a faint trace of arsenic. The condition of the patient became gradually worse, the weakness of the limbs increasing, and there being in addition considerable general wasting. On making a detailed examination on Nov. 29th the following state of affairs was noticed. The patient lay on her right side in a drowsy, heavy condition, with the eyes half open and the knees drawn up. She opened her eyes slowly when asked to do so. She could recognise me, mentioning my name. She complained of her head, saying that it felt as though drums were playing in the street. Dark brownish pigmentation of the skin was present on the neck, the axillæ, the abdomen, the thighs, and the legs. There was flaky desquamation of the skin over the lower part of the abdomen. Over the calves of the legs the skin was roughened and desquamating. The legs and hands could be moved slightly without the patient being roused, but on making more extended movements she complained of pain. The left foot was dropped and the skin was thickened; on the right foot keratosis was well marked, especially over the heel. The patellar reflex was absent on both sides. The tongue was red and moist, the pupils reacted readily to light, the eyes were somewhat watery, but there was no nasal discharge. The heart sounds were regular but feeble, the first sound was hardly to be detected. The pulse was 100 per minute and exceedingly feeble. The respirations were 24 per minute; there was slight movement of the diaphragm. The chest moved as a whole without much lateral expansion. The temperature was normal. During the five days ending on Dec. 4th the patient's condition remained much the same though more nourishment was taken and the comatose state was not so well marked.

Pendleton.

SYMPTOMS OF ARSENICAL POISONING PRODUCED IN A YOUNG CHILD BY DRINKING BEER.

By JOHN BROWN, M.D. VICT., D.P.H.,

MEDICAL OFFICER OF HEALTH OF BACUP.

DURING the recent epidemic of peripheral neuritis, now proved to have arisen from the drinking of arsenicated beer, I have seen no reference to any cases observed in very young children. Such must be of very rare occurrence, as it is to be hoped that parents do not generally allow young children to drink beer. Moreover, if a case occurred in a child it would most probably not be easily detected, as it is a condition one would hardly expect in a young child. On Nov. 27th, however, whilst attending a patient affected with peripheral neuritis my suspicions were aroused to the case which I now record, and I was led to suspect that the child was suffering from arsenical beer poisoning by the fact that the father had peripheral neuritis. Dr. Kelynack, to whom, with Mr. Kirkby, is due the credit of being the first to announce to the profession the true source of the arsenic, very kindly came to Bacup to see the patient with me. He went over the case very thoroughly and expressed his opinion that it was undoubtedly a distinct but mild case of peripheral neuritis due to arsenical beer. The case being unique I have made a few notes briefly recording the more important features.

The patient was a bonny-looking little girl, aged two years. She had been unwell for some days, suffering from pains in the feet, legs, and arms which were thought to be rheumatic pains. Evidently her feet felt hot and uncomfortable, for she wanted her shoes always off. The child was too young to describe her subjective symptoms, so that it was necessary to rely on the objective ones. Her face was flushed, her eyes were watery, and there was a slight running from her nose. The cutaneous symptoms were as follows. There was no pigmentation of the face, neck, thorax, axillæ, abdomen, or groin. Erythematous areas existed over the arms and forearms in the region of the elbows, being most marked on the extensor surfaces. The palms of the hands were red, especially over the thenar and hypothenar eminences and about the tips of the fingers. In the lower extremities there was marked erythema over both knees, and on the right side above the patella there were several distinct, irregular, brownish patches, evidently due to pigmentation in the superficial layers of the skin and not arising from effusion of blood. There were similar pigmented spots above the left knee, but neither so well-marked nor so extensive. There was erythema of the soles of the feet and the toes, with a distinct border to the erythema along both sides of the feet and around the heels. As the child sat on the lap of a relative the feet looked "dropped" as if the extensors were paretic, but there was no distinct paralysis. There were no impairment of the tactile sensation, no muscular hyperæsthesia, no plantar reflex, and no dorsal extension of the toe; the knee-jerks were absent.

---

[2] THE LANCET, March 17th, 1894, p. 669.

Remarks.—The child's father keeps a public-house, and although so young she was accustomed to get little "sups" of beer from the kindly disposed customers at the bar. I have carefully tested samples of the beer and have found arsenic present. In four distinct cases of peripheral neuritis occurring in Bacup I have examined the beer and have found arsenic in each case. Out of 14 different samples of beer no less than 11 showed distinct traces of arsenic No doubt many cases of peripheral neuritis due to arsenicated beer have been overlooked.

Bacup.

NOTES OF TWO CASES OF FOREIGN BODY IN THE AIR-PASSAGES.

By E. F. SYRETT, M.D. DURH., M.R.C.S. ENG.

THE following two cases occurring within a few months of one another are of interest on account of the entire absence of urgent symptoms, and the fact that in neither case was the presence of a foreign body suspected.

CASE 1.—On May 12th, 1900, I was called to see a boy, aged 13 years, who, I was told, had been ailing for three weeks. The symptoms complained of were cough, fever, and pain over the base of the right lung. His temperature was 103° F. and his cheeks were flushed. Examination of the chest showed a markedly impaired percussion note over the whole of the right lung. The vesicular murmur was deficient, and at the apex of the lung, both behind and in front, moist sounds were heard. The left lung showed nothing but increased breath sounds. The sputum was abundant and blood-stained. Cough was frequent, but there was nothing remarkable in its character. The patient was kept in bed for two weeks and was allowed to get up when the temperature fell to normal. The physical signs remained unaltered and the cough continued, but the patient seemed quite bright and well. I continued to see him about once a week during the next two months, his condition remaining unaltered. On July 26th, whilst trying to pull a stick away from a large dog he had a violent attack of coughing and he coughed up a small smooth pebble a little larger than a cherry-stone. On cross-examining the mother she said that at the time the cough, &c., commenced the boy while playing football had put the stone into his mouth "to keep his wind." On returning from the game he told her that he had swallowed the stone, but beyond an attack of coughing at the time he had felt no ill-effects. The symptoms which supervened she attributed to catching cold during the game. The stone was, therefore, retained in the right bronchus just 13 weeks.

CASE 2.—This patient, a married woman, aged 33 years, came to me on account of toothache on Sept. 12th, 1900. I sent her to a dentist and a lower wisdom tooth was extracted on the next day under gas. On the 14th she came to me with complaints of cough and hoarseness. She said that on recovery from the gas her lungs felt blocked up, and she had been coughing considerably all night. On examination of her chest I found universal rhonchus, with a few moist sounds, both lungs being equally affected. There was no dulness. She was expectorating blood-stained sputum. I advised her to go to bed and an elaborate treatment for bronchitis was carried out. In spite of everything the bad symptoms increased. On the 25th, 12 days after the extraction of the tooth I called to see the patient, and she told me that she was better. A violent fit of coughing had expelled the wisdom tooth, which I at once recognised as the old offender.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.

A CASE OF ABSCESS OF THE LIVER DIAGNOSED BY THE PRESENCE IN THE URINE OF CRYSTALS OF CHOLESTERIN, LEUCIN, AND TYROSIN.

(Under the care of Dr VINCENT DORMER HARRIS and Mr. J. F. C. H MACREADY.)

THE association in the following case of the presence of leucin, tyrosin, and cholesterin in the urine with impairment of the percussion note over the lower part of the right lung, was strongly suggestive of some active process in the liver. We are not aware that it has been noticed that abscess of the liver is often accompanied by the presence of these abnormal constituents in the urine. It is not improbable that they might be found in small quantities in many acute morbid conditions of the liver if they were specially sought for. For the notes of the case we are indebted to Dr. J. G. Emanuel and Dr. E. W. Martin.

A sailor, aged 48 years, was admitted into the City of London Hospital for Diseases of the Chest, Victoria-park, E., under the care of Dr. Vincent D. Harris on Jan. 15th, 1900, complaining of pain in the right side of the chest and of having lost flesh. The symptoms had started insidiously and without any obvious cause some three months previously and had been getting gradually worse up to the date of his admission. In October, 1899, the patient's weight was 12 st. 7 lb., whilst on his admission he only weighed 9 st. 10 lb.—i.e., the patient had lost nearly three stones in three months. The pain on the right side was not severe, but it was constantly present and of a gnawing character, and was evidently telling very seriously on the patient's general constitution. The pain was not affected in any way by eating, by respiratory movements, or by exertion. It was localised to the right side of the chest, over a somewhat indefinite area, corresponding to the lower part of the right axilla. There was no tenderness of the painful area even on deep pressure.

The previous history showed uninterrupted good health till the year 1896, when the patient was laid up in South America for four weeks with a severe attack of dysentery. Twelve months or so after this, when in England, he had another less severe attack, and again in 1898, whilst in South Africa, he was laid up this time for three weeks with dysentery. In each attack diarrhœa with blood in the stools was a prominent symptom; in the intervals between these attacks the patient's health had been excellent and he had enjoyed perfect health since the last attack in 1898, up till three months before his admission into hospital in 1900.

On examination the patient was found to be a middle-aged man, emaciated, and with a somewhat ashy-grey complexion, lying comfortably in bed in any posture. He had a rather cachectic appearance, suggestive of malignant disease, but otherwise he presented no obvious morbid appearance. The temperature, pulse, and respiration were normal. Examination of the heart revealed nothing abnormal, and he had no shortness of breath even on exertion. His lungs were free from abnormal signs, with the exception that the percussion note at the right base was impaired below the angle of the scapula, and over this area the breath sounds were weak (they were distinctly audible, however, as far as the extreme base), and tactile vocal fremitus and vocal resonance were diminished. The percussion note and entry of air over the right base in the axilla and anteriorly were good. He had an occasional slight cough, accompanied by a very little mucoid expectoration. His tongue was clean, the appetite was good, the bowels were regular, and he had no pain or discomfort of any kind with his food. The abdomen was readily palpable and there was no enlargement of the liver or spleen. The upper border of the liver dulness corresponded to the fifth rib in the right vertical nipple line and to the seventh rib in the right axilla. The lower border of the liver dulness corresponded to the costal margin in the right vertical nipple line. The urine was acid, of specific gravity 1020, contained a very faint trace of albumin, and gave the blood reaction with ozonic ether and guaiacum. On microscopic examination it was found to contain a number of red blood corpuscles and crystals of leucin, tyrosin, and cholesterin, the latter in considerable abundance. The patient slept well and exhibited no abnormal symptoms or physical signs suggestive of cerebral disease of any kind.

In picking out the salient features of this case for the purpose of diagnosis the following appeared to be the most important points: (1) the remarkable condition of the urine; (2) the signs of slight pressure on the lower lobe of the right lung; (3) the history of dysentery; and (4) the patient's general condition, indicative of some serious lesion. The condition of the urine did not seem to be associated with any actual disease of the kidney or bladder, as there were no signs of casts, no marked diminution in the elimination of urea, and no increased frequency of micturition. On the other hand, the condition of the urine immediately brought to mind the character of the urine in cases of acute yellow atrophy of the liver, and it suggested very forcibly some destructive process going on in the liver. This, taken together with the history of dysentery and the signs of pressure on the lower lobe of the right lung, suggested the possibility of the presence of a dysenteric abscess of the liver, and with this thought constantly in mind the patient was kept under careful observation for several weeks. His condition, however, did not seem to alter in any appreciable degree. His weight remained stationary and his temperature slightly subnormal, he ate and slept well, and he was able to walk about in the grounds of the hospital with the convalescent patients. He always, however, complained that the pain in his right side "got no better" and that he became easily tired. Moreover, his appearance did not change and he always gave the impression of having something seriously amiss. His physical signs remained absolutely unaltered and he was regularly examined at least once a week with a view to finding some change in the physical signs. The character of the urine also remained the same as on admission excepting that the trace of blood found on admission was often not detectable by the chemical tests, and the faint trace of albumin was not always present. Crystals, however, of leucin, tyrosin, and cholesterin were present at every examination, and for some weeks the urine was examined microscopically every other day.

Towards the end of March, ten weeks after the patient's admission, some slight œdema over the lower ribs in the right axilla was discovered, and then for the first time it was noticed that there was some bulging of the ribs at this slightly œdematous part. Accordingly, on March 27th into the centre of this area (in the seventh space in the mid-axillary line) an exploring needle was inserted and a syringeful of chocolate-coloured pus was withdrawn. The pus was quite odourless and microscopically consisted of pus cells, granular débris, and fatty globules; no amœbæ were found on the warm stage of the microscope. Three days later (March 30th) Dr. Martin anæsthetised the patient, while Dr. Emanuel resected part of the eighth rib in the right mid-axilla. After the rib was removed a thick membrane presented, and this was taken to be the pleura, diaphragm, and peritoneum fused together by chronic inflammation. Into this membrane an exploratory needle was inserted and chocolate-coloured pus was again withdrawn. The membrane was then incise and a little more than a pint of this odourle chocolate-coloured pus escaped. A finger inserted into th wound passed into a large abscess cavity in the liver, wit soft velvety walls, freely bleeding after any manipulation. drainage-tube was inserted and dressings were applie Subsequently the wound was dressed daily. The discharg rapidly diminished, the tube was gradually shortened, an the patient made an uneventful recovery, leaving the hospit on May 24th perfectly well in every respect and weighin 11 st. 5 lb. (being a gain of 1 st. 9 lb. in the seven wee following the operation). The patient reported himself tw months after his discharge and said he was perfectly we and about to sail for China. Very soon after the evacuati of the pus the leucin, tyrosin, and cholesterin crystals di appeared from the urine and the urine became quite normal

Remarks by Dr. EMANUEL *and* Dr. MARTIN.—We ventu to believe that this case is worthy of publication on accou of the following facts: 1. The presence of cholesterin i urine is rare and its association with leucin an tyrosin is still more uncommon. These three constituen were constantly present in the urine of the above case f ten weeks to our knowledge, but disappeared as soon as th hepatic abscess was drained. These facts evidently therefo justified our opinion in associating their presence with som destructive process going on in the liver. 2. The liver absce on the patient's admission was deeply situated an it gradually pointed to the thoracic wall, because o four different occasions during the ten weeks before th operation an exploring needle was inserted into the ches without result, two explorations being made in the back i the ninth space in the scapular line, and the other tw explorations being made in the right axilla in the sam space and at the same spot, where the exploration mad subsequently on March 27th discovered the pus. 3. The cas exemplifies the fact that a chronic abscess of the liver ma be associated with no fever—the temperature througho was subnormal. 4. There was an interval of two yea between the last attack of dysentery and the first sympto of the liver abscess

CONNAUGHT HOSPITAL, ALDERSHOT.

CASE OF ACUTE PNEUMONIA WITH HYPERPYREXIA; BENEFICIAL EFFECT OF OXYGEN.

(Under the care of Mr. A. ALISON BRADBURNE, Civil Surgeon Army Medical Service.)

THE exact value of oxygen in the treatment of pneumonia cannot be said to be fully determined. That it is useful for sudden and severe attacks of dyspnœa is now generally acknowledged, but that it is of any real value in cutting short the attack or reducing the temperature is more than doubtful. The ordinary methods of administering the gas are by no means satisfactory and it is not probable that the percentage of oxygen in the inspired air is very much increased.

A man, aged 24 years, was admitted into the Connaught Hospital at 12 noon on May 29th, 1900. The temperature was 106° F., the pulse was 112, and the respirations were 38. There were physical signs of pneumonia commencing in the right lung and crepitations were heard from the apex to the base; in front and behind. Slight mental excitement and tremors were present. An effervescing cough mixture was prescribed; also to endeavour to reduce the temperature powders containing a grain each of quinine and phenacetin were given every half-hour. He was also sponged every half-hour. When seen two hours after admission (2 P.M.) the temperature, despite the treatment, remained the same, and the patient had vomited as soon as he was given the medicine and powders; they were consequently discontinued and reliance was placed on cold sponging, which by 2 A.M. on the following morning had reduced the temperature to 101·4°. When seen at 10 A.M. on the 30th the temperature stood at 105·6° and rose, despite sponging, to 105·8° by 2 P.M., at which hour the patient was given a cold pack (made with tepid water), in which he was left for an hour. At 4 P.M., the temperature being still 105·6°, five grains of phenacetin were given in hot whisky and water. This was followed by a gradual decline to 101·4°, which was reached at 10 P.M., when the temperature again commenced to rise. On the 31st the temperature at 6 A.M. had reached 103·8°, for which five grains of phenacetin were given, but this time it was followed by a rise to 105·8°. It only seemed possible to keep the temperature stationary for about four hours at 103·8°, then another five grains caused a small drop which lasted exactly an hour, to be followed by a more intense rise to 106·2°, which was registered at 4 P.M. The thermometer was used every half-hour and when it was found to register this height another five grains of phenacetin were given, and this, combined with the steady sponging which all along had been used in conjunction with the antipyretic, effected a reduction in the temperature to 102·4°. The mental excitement noted on admission had passed into the stage of active delirium, necessitating careful watching. On June 1st the temperature at 6 A.M. stood at 104·2°. The pulse was 120 and the respirations were 48 An enema which acted well was given. The chest symptoms were following the usual course, but a roughened sound over the pulmonary area had developed, indicating some pleuro-pericarditis on the left side. This luckily cleared up as the disease progressed and caused no trouble. The pulse remained fairly strong, despite the numerous doses of phenacetin, to counteract which and to assist the heart 15 minims of tincture of digitalis with five minims of solution of strychnine and five minims of diluted nitro-hydrochloric acid had been given every four hours; four ounces of brandy were also given during the 24 hours. Another attempt to give quinine was tried in a mixture with 10 minims of tincture of opium, but, as on previous occasions, it was immediately rejected. On the 2nd at 2 A.M. the thermometer registered 105·8° which phenacetin successfully reduced to 101·8°, and as the stomach was beginning to be irritable all medicine by the mouth was stopped. The milk, which the patient was taking fairly well, was partially peptonised, and by these measures all vomiting ceased. To replace the medicine and to assist the respirations, though the signs of cyanosis were very slight, inhalations of oxygen for periods of ten minutes at intervals of half an hour were commenced, and when seen 24 hours later the improvement, especially in the state of the pulse, was most gratifying, even though for that period the patient had taken no medicine whatever. To assist liquefaction of the bronchial secretion poultices were applied along with the use of the steam kettle containing compound tincture of benzoin and turpentine. The bowels had acted once and the urine had been passed involuntarily. During the night of the 2nd and the morning of the 3rd the temperature stood steadily between 103° and 104° Unfortunately, the oxygen gave out about midday, after 24 hours' use, and the tubes which had been telegraphed for did not arrive until late in the afternoon, when it was again resumed. To make up for the absence of oxygen and to anticipate the effects of a hoped-for and expected crisis hypodermic injections of three minims of solution of strychnine every four hours alternated with five minims of ether were given. At 10 P.M. the crisis commenced, the temperature falling in one and a half hours to 99°. Naturally such a rapid fall necessitated strong stimulating remedies. The patient was given an enema containing brandy, digitalis, and strychnine, which was returned, but a second enema was retained; also hypodermic injections of ether and strychnine were administered. He passed a restless night, but the pulse, which had nearly failed, recovered itself by next morning. A source of trouble was the patient's refusal to take nourishment by the mouth, so rectal feeding was therefore resorted to and continued during the night until midnight, when he asked for something to drink, so enabling the nurse to give him some milk. On the 4th the patient was decidedly better and the hypodermic injections were stopped, being replaced by tincture of strophanthus. There was no vomiting and the bowels acted well. The oxygen was also stopped. He was still delirious, but was not troublesome. The temperature, instead of remaining down, as was hoped, rose to 101°, and by midday it had reached 103°, but from this point it steadily fell to normal, which it reached on the evening of the 6th. On the 5th 10 grains of sulphonal were given to enable the patient to get some rest and to quiet his delirium, and this was followed by a very satisfactory period of what looked like natural sleep. There was very little expectoration, a feature which marked the whole course of the disease, though at this stage moist râles could be heard all over his right chest. By the evening of the 6th the temperature had dropped to normal, and remained so until the 11th, when it rose to 99·8°, falling to 98·4° on the same day, which was caused most probably by the great heat experienced that week. After so much delirium and hyperpyrexia it was not to be wondered at that the patient should exhibit some signs of mental weakness for a few days, but all these cleared up satisfactorily and he made a complete recovery.

Remarks by Mr. BRADBURNE.—This case presents one or two points of interest, the chief being the great tendency the temperature showed to run up to a high reading along with the great difficulty experienced in endeavouring to reduce it; also worthy of note is the antipyretic action of phenacetin without any seemingly weakening or depressing action on the heart—true, it was always given in whisky. Yet another point of interest was the way the patient's system immediately rejected all forms of quinine. This antipathy to the drug was a drawback, for had we been enabled to use frequent small doses of phenacetin and quinine (as recommended by Yeo) there is little doubt but that we should have been enabled to keep the temperature within bounds. The final and most satisfactory incident in the whole case is the gratifying results which followed the use of oxygen, and it was the early and steady employment of it that acted as the main factor which led to the ultimate recovery of the patient. It was fortunate that a patient exhibiting such symptoms had youth and a good constitution to assist him and us, and it must not be forgotten that part, if not the greater part, of our success was due to the most excellent and painstaking nursing which the patient received.

By the kind permission of Lieutenant-Colonel J. Wilson, R.A.M.C., officer in command of the Connaught Hospital, I am permitted to record the above case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Parasitology, Etiology, and Prevention of Malaria.

A MEETING of this society was held on Dec. 11th, Dr. F. W. PAVY, the President, being in the chair.

Dr. PATRICK MANSON communicated a brief *résumé* of the recent advances in the Parasitology of Malaria. He began by remarking that when this subject had last been discussed, in 1896-97, the cycle through which the malarial parasite went in the human body had been recognised, but the cycle external to the body had not been studied. How it was introduced was not known, but since the organism was a blood parasite some blood-sucking animal was suspected as the means of infection, and there were epidemiological and geographical reasons which pointed to the mosquito. Surgeon-Major Ross was one of the earliest disciples of the mosquito-malarial hypothesis, and he then set to work and after two or three years' indomitable perseverance he conclusively proved the truth of this theory. Ross first studied the evolution of the coccidium Schubergii in bird malaria and found there was an endogenous and an exogenous phase. Then turning his attention to the hæmomenas præcox, the parasite of æstivo-autumnal fever, he found it to be strictly analogous. The evolution of this malarial parasite in the blood of man was asexual, it entered the red blood cells, developed, was liberated, and the new generation attacked other blood-cells Outside the human being, however, the parasite developed in the body of the mosquito as a bi-sexual organism. The place of the malaria parasite in zoology was then discussed, and recent observations on the evolution of eimeria and coccidium by Pfeiffers, Simond, and Schuberg were referred to. The eimeria was the endogenous phase of the coccidium. The nomenclature was very confusing; some bodies had several names, others had no names at all. Reform in this respect was urgently needed. Two things were required to complete their knowledge of the entire life-history of the malaria parasite—namely, first, what circumstances determined the distinction of the merozoites, and whether they proceeded to the mosquito phase (the bisexual cycle) or to the human phase (the Golgi cycle); and secondly, what became of the parasite during the long latent period which sometimes elapsed between exposure to infection and the development of attack. An explanation was also wanted as to why crescents were so frequently found in this country and (in the late autumn) in Italy, and so rarely in tropical Africa, and in Italy during the summer and early autumn. Turning next to the various kinds of mosquito concerned in the conveyance of infection, hitherto only anopheles had been implicated in malarial infection and of this there were 46 known species. Of these the parasite had been found in anopheles funestus, costalis, claviger, pseudopictus, superpictus bifurcatus, and the as yet unidentified species of Ross. There were 250 species of culex known, none of which was known to be an efficient carrier of the malaria parasite, though very few had been tested—namely, culex mimeticus, pipiens, tæniatus, nemorosus malariæ, and three unidentified culices experimented with by Daniels in British Central Africa. Much attention had been bestowed of late on what was supposed to be a phase of malarial intoxication—namely, blackwater fever. One German and two English expeditions had been sent to investigate it. Results as regard the etiology of the disease had been *nil*, although much useful information had been gathered bearing on blackwater fever and also on malaria. The geographical range was found to be more extensive than was generally supposed. As regards malaria, children were found to be specially susceptible to the disease, as many as 70 or 80 per cent. of native children under one year of age contracting the disease. The proportion infected became gradually smaller as age advanced until 10 or 12 years old. An immunity seemed to be obtained in some way among the native population. Reference was made to the post-mortem findings of Hill and Daniels in Demerara. The former observer showed that out of 45 deaths from malaria in Georgetown Hospital between June, 1893, and June, 1895, in persons born in the colony 31 were under 13 years of age and only three over 21 years. Practically all deaths from malaria occurred in children. Daniels in a series of 1289 post-mortem examinations from 1893 to 1895 found malarial pigment in none under a month old. It was present in 25 per cent. of those over one month and under 12 months, in 54 per cent. in those over one year and under two years, in 81 per cent. in those over two years and under five years, whilst in those above 30 years of age it was only found in 18 per cent. and in gradually diminishing proportions in each ascending decade. The conclusion drawn by Daniels was that immunity was acquired by the young in that district probably by previous attack. Turning once more to blackwater fever the theory that it was caused by quinine was untenable, for many persons had the disease who had not had quinine. Nor was it an intense form of malaria, for the evidences of malarial infections were commonly absent and the fever was not always found in intensely malarial places; nor was it a malarial cachexia, because it might occur within a few weeks of arrival in a malarial country. The suggestions that blackwater fever might be due to a special type of malaria parasite, or it might be due to a malaria parasite the virulence of which was increased by being transmitted through a particular species of mosquito; or it might be a disease *sui generis*, were tenable but they lacked confirmation. As to the prophylaxis of malaria there were four means available—to avoid natives, to take quinine, to destroy mosquitoes, and to protect from mosquitoes. These measures were efficient but were not always applicable. Complete protection was perhaps impracticable, but relative protection was always possible and was of immense value.

Dr. L Sambon and Dr. G. C. Low gave an account of the experiments conducted on behalf of the Colonial Office and the London School of Tropical Medicine in the Campagna and in London. It was pointed out that the hypothetical connexion between mosquitoes and ague was a very old belief amongst the ancients and had long existed amongst the savage inhabitants of certain malarial areas in the tropics (in East Africa, for instance), where the word *mbù* indicated both the fever and the gnat. The discovery by Dr. Patrick Manson 20 years ago that the mosquito was the intermediate host of filaria Bancrofti, and the more recent discovery by Smith and Kilborne that pirosoma bigeminum was propagated by a common tick of cattle, supported the theory by analogy. The experiment about to be described was decided upon by the Colonial Office on the recommendation of their medical officer, Dr. Manson, who himself planned the experiment so that it might prove in a most convincing manner the truth or error of the mosquito malarial theory and in order to ascertain how far the necessary protection might be consistent with the ordinary avocations of life. It consisted of two tests—one to prove the theory in a positive manner, the other by negative interference (should they both succeed) In the first test it was provided that a man should allow himself to be bitten by mosquitoes reared and infected in a malarious region and then sent home. In the second test two men who had never suffered from malaria were to go into one of the regions known to be undoubtedly malarious and live there throughout the fever season with no other protection than such as might prevent the bites of mosquitoes, for which purpose they would be provided with a mosquito-proof hut. For the first part of the experiment a supply of insects which had fed on a patient suffering from benign tertian fever was sent out in batches. Considerable difficulty was experienced in packing them successfully, but at last all the difficulties were overcome and an ample supply of anopheles was sent home from Italy. Mr. P. Thurburn Manson, Dr. Patrick Manson's son, was bitten by these insects and developed the typical symptoms of double tertian ague. Some little time after this Mr. Warren, an attendant in the laboratory at the London School of Tropical Medicine, subjected himself to the bites of the third batch of mosquitoes. He likewise underwent a severe attack of benign tertian fever. The notes of both of these cases were read. As regards the second part of the experiment Dr. Sambon and Dr. Low were sent out to the Roman Campagna where they lived in a mosquito-proof hut during the whole of the fever season, extending from July 19th to Oct. 19th. Two other persons also lived with them in the house. The place chosen was Ostia, a part of the Campagna known to be the most intensely malarial. All the inhabitants around suffered from malaria, and out of 14 or 15 healthy police who were sent down into the district all contracted the malady. The four inhabitants of the hut, however, remained perfectly well all the time and afterwards up to date. The hut was fully described. It was built by Messrs. Humphreys and contained six rooms. The windows and all the crevices were protected by wire netting having meshes of 17 millimetres. The windows were left wide open day and night. The occupants all went out daily for long excursions into the Campagna. At first they took care not to go out before one hour after sunrise and after one hour before sunset. They found that the risk of being bitten during the day was infinitesimal. At first they wore veils but found them to be unnecessary. The flies were very troublesome but they were never bitten by mosquitoes. They studied the habits of the anopheles claviger and the anopheles pseudopictus. The habits of these animals were then described. Finally, Dr. Sambon and Dr. Low gave as their conclusion that these experiments proved beyond a doubt that mosquitoes, and only mosquitoes, were capable of transmitting malarial fever, that protection from their bite implied absolute immunity, that the protection was easily obtained, and did not in any way interfere with the ordinary avocations of life.

Mr. D C. Rees exhibited various phases in the Mosquito Cycle of the Malarial Parasite and specimens of the Anatomy of the Mosquito.

MEDICAL SOCIETY OF LONDON.

The Diagnosis and Treatment of Thoracic Aneurysm

A meeting of this society was held on Dec. 10th, Mr. John H. Morgan, the President, being in the chair.

Dr. J. Kingston Fowler resumed the discussion on the Diagnosis and Treatment of Thoracic Aneurysm[1] He remarked that the diastolic thud was a sign of the greatest diagnostic value, since it was present in no other condition Tracheal tugging also, when present, invariably indicated aortic aneurysm. He had lately seen a case in which the absence of tracheal tugging helped to exclude aneurysm The only fallacy of this sign was when there was a new growth almost surrounding the aorta and attached to the trachea; movement might thus be communicated. He had not had very much experience with the Roentgen rays, but he had not seen a case which could not be diagnosed otherwise. A 10 inch spark and first-class apparatus were necessary to elicit the outline of an intra-thoracic aneurysm. As regards Tufnell's treatment it was difficult to lay down general rules. Seven ounces of solids and eight of fluids were the quantities he had adopted. The longest time he had seen it carried out faithfully was three months. He referred to a case which he had seen some years ago of abdominal aneurysm in which the patient had died from rupture of the tumour. At the necropsy it was found that no clot had formed in the sac. The presence of aortic regurgitation, he thought, was certainly a contra-indication to this treatment, and he referred to a patient in whom the left ventricular compensation began to fail as a consequence of the treatment; intra-cardiac thrombi formed and, becoming dislodged, caused death from embolism. The presence of a distinct to-and-fro murmur, combined with hypertrophy of the left ventricle, might be regarded as certain evidences of aortic regurgitation. Uncomplicated aneurysm very rarely led to hypertrophy of the left ventricle or to a double aortic murmur such as that of regurgitation. The treatment of aneurysm very often consisted of several factors and it was difficult to decide which was the most important. Rest and iodide of potassium were very efficacious in the relief of pain. If no improvement took place by these means he then added a modified Tufnell diet. Turning to Lancereaux's method he had seen three cases treated on this plan. The first was a male, aged 44 years, with aneurysm of the ascending aorta of sudden onset and six months' duration without a history of syphilis. The patient was a road-scraper who attributed the disease to a blow on the sternum. There were aortic regurgitation and tracheal tugging. The injections were used on seven occasions. On June 2nd 150 cubic centimetres of a 2 per cent. solution and on the 6th 150 cubic centimetres of the same strength were injected. The temperature went up to 102° F. and he was restless for two days. The injections were repeated on the 21st. On June 25th and August 1st 60 cubic centimetres of a 5 per cent. solution were injected. On August 10th and 22nd 200 cubic centimetres of a 5 per cent. solution were injected. The patient left the hospital on Nov. 1st and attended as an out-patient. There was nothing particularly interesting in his case. Seven injections were a very small number. Another case was that of a female, aged 48 years, with aneurysm of the transverse aorta, the duration of which was two years. There was no aortic regurgitation She had injections on May 24th and June 11th of 150 cubic centimetres of a 2 per cent. solution into the buttock. On June 16th she had a good deal of neuralgic pain and on the 17th she was taken suddenly ill with vomiting and shortly after with profuse sweating at 4 P.M At 6 30 P.M. she became unconscious, was blanched and cold. There was no alteration in the physical signs. There were no convulsions. In the evening she became less unconscious. On the 18th consciousness returned and she complained of severe pain at the back of the head and down the neck. Next day (the 19th) there were constant yawning and sighing, with persistent pain in the back of the head. These symptoms pointed to blocking of the internal carotid and subsequent re-establishment of the circulation. There was no evidence of embolism of either the middle or the anterior cerebral artery. The third patient, a carman, aged 52 years, was under the care of Dr. W. Cayley. There was an aneurysm of the transverse aorta forming a large tumour projecting between the first and fifth costal cartilages There was no history of syphilis. He had had rheumatic fever in 1891. The symptoms of aneurysm had first begun in 1895, the swelling having appeared in 1898. He had been submitted to a restricted diet with benefit and had returned to work, but the symptoms came on again, and finally he went into the Middlesex Hospital, where in July he had 15 injections, gradually increasing in strength, beginning with 220 cubic centimetres of a 2 per cent. solution at a temperature of 99° and increased up to a 20 per cent solution. There was pain after all of the injections with a rise of temperature after some. The pulsation appeared to be somewhat less, but the tumour was not diminished in size and the skin over it was so thin that it threatened to burst. Dr. Cayley had informed him that in his opinion no benefit had resulted from the injections. His (Dr. Kingston Fowler's) experience was not very favourable to the treatment. The first of the three patients had probably been benefited and he thought that when there was an aneurysm of the ascending part of the arch with a small orifice of entrance it might be useful. But, on the other hand, where there was a very large sac containing no clot, with a large orifice of entrance, neither restricted diet nor Lancereaux's method would be of much benefit. As regards tracheotomy it was of course no use when there was direct pressure on the trachea. He referred to a case under the care of the late Sir George Johnson when a bilateral spasm of the adductors had existed due to pressure on one pneumogastric nerve. The patient had severe attacks of dyspnœa and tracheotomy was performed by the late Sir William Ferguson with considerable benefit Inhalations of oxygen and the injection of morphia were useful in those cases where spasm existed. The prognosis of aneurysm, he believed, was better than was generally thought, and he referred to several cases which had lived for years—one for 13 years, another for six years, and another for nine years.

---

[1] Vide The Lancet Dec. 1st, 1900, p. 1575.

Dr. Robert Maguire wished to emphasise the importance of the apparatus employed in transfusion, for it was of the greatest importance to introduce the gelatin solution as rapidly as possible

Dr. T. Gilbart Smith had seen the patient referred to by Dr. de Havilland Hall At first he had suspected aneurysm but subsequently had been doubtful about it There was no paralysis of the left vocal cord. The larynx was twisted over and the symptoms pointed to laryngeal trouble from some other cause It appeared to him like a case of shrunken lung which had retracted from the front of the heart and the accentuated second sound had appeared to him to be of pulmonary origin He referred to a patient with a dilated pulmonary artery due to a retraction of the lung presenting many [illegible] the symptoms of aneurysm which had made him suspect that condition in this case. But when he saw the case two years ago he then came to the conclusion that after all it must be one of aneurysm. Referring to the Roentgen rays he had seen several cases in which undoubtedly that method was of considerable help and by its means malignant disease had been diagnosed which was previously unsuspected. He had seen several cases treated by gelatin injections, but on the whole they were not distinctly benefited by them. He had long ago given up Tufnell's treatment, for there was not sufficient benefit in return for the misery which it entailed. He thought that the rigid rest and starvation reduced the resisting power of a patient's vitality. He referred to a case in which aneurysm was complicated by locomotor ataxy. Tracheotomy was no use unless the obstruction existed in the larynx and the real question was whether the surgeon could dilate the constriction below.

Dr. Seymour Taylor thought that it would have been useful if the question of the diagnosis between aneurysm and intra-thoracic growths had been discussed. The cardinal symptoms of aneurysm were really only four or five in number. All the others were common to aneurysm and new growths in the thorax. Thrill was a very valuable sign in the diagnosis of aneurysm, and it generally meant that there was little or no laminated clot This and the diastolic shock were conclusive signs to his mind. The "whiffing" sign, which could be heard with every pulsation of the heart when the trachea was pressed upon, was another sign of value. He did not attach very great importance to tracheal tugging. It might occur with cardiac hypertrophy and it was by no means constant in aneurysm. As to treatment, he had not seen the slightest benefit from Tufnell's treatment. He believed that it lowered the tone and the resisting power of the patient Tracheotomy was no use unless the dyspnœa was due to spasm of the vocal cords.

Dr. Kingston Fowler explained that he did not intend to imply that tracheal tugging was present in all cases It could only be elicited when the aneurysm was in contact with the trachea or the main bronchus.

Dr. Edmund Cautley thought that the reason why Tufnell's treatment was not generally successful was because it had been employed in unsuitable cases If cases among the lower orders, especially with a history of alcoholism, were submitted to it they failed, but in cases of simple sacculated aneurysm occurring among the better classes who would cooperate intelligently it was successful, and he referred to a case in which the patient after 10 weeks' treatment had made great improvement, and after 21 further weeks of modified diet had recovered sufficiently to ride and to shoot; the only thing he could not do was to walk fast. Insomnia and a difficulty in passing his concentrated urine were the only troubles of which this patient had complained. He referred to another case which had greatly improved under the diet and calcium chloride.

Dr. F. de Havilland Hall, in reply, laid stress upon the fact that the absence of tracheal tugging was, in his opinion, of value in showing absence of aneurysm. He did not believe that iodide of potassium alone was as successful as when combined with a restricted diet. He would like to see the effect of iodide of potassium tried while the patients were up and about. As regards the length of time during which Tufnell's treatment could be carried out seven months was the longest that he had seen in a patient who had then been sufficiently well to return to his work on the Stock Exchange. Shortly afterwards he exerted himself violently and died suddenly. He had not been impressed with the value of Lancereaux's treatment, but he thought it was too early to judge in the matter because cases of aneurysm went on for years.

OBSTETRICAL SOCIETY OF LONDON.

The Treatment of Retroflexion of the Gravid Uterus.—A New Theory of the Causation of Sex.—Exhibition of Specimens.

A MEETING of this society was held at 20, Hanover-square, W., on Dec. 5th, Mr. ALBAN DORAN, the President, being in the chair.

Dr. W. J. SINCLAIR read a paper on a Contribution to the Diagnosis and Treatment of Retroflexion of the Gravid Uterus. He pointed out that in a typical case of retroflexion of the gravid uterus the symptoms produced a *tout ensemble* which was quite characteristic and made diagnosis easy and certain. The striking constant feature was irritability of the bladder with more or less retention of urine. The contributions to the journals on the diagnosis and treatment of the condition had a tendency to exaggerate the frequency of complications, and the literature of the subject seemed to indicate a too ready resort to operative treatment. The special method of treatment which Dr. Sinclair advocated was extremely simple. It consisted essentially in the introduction of a watch-spring pessary, care having previously been taken to empty the bowel and bladder. After the introduction of the pessary, if the patient were made to rest on her side, lying over with her face downward as far as she could with comfort, it would be found that the action of the pessary alone would restore the uterus to its normal position in a few hours. Illustrative cases were given. The whole number of cases in which the method of treatment had been tried by Dr. Sinclair was 15. These had been consecutive and in all the method of treatment had been successful. One case was mentioned in which the watch-spring pessary treatment was adopted owing to a misunderstanding in a case of fibroid tumour attached to the fundus uteri, which had fallen back into Douglas's space and produced the bladder symptoms of retroflexion of the gravid uterus. In this case the action of the pessary raised the tumour into the abdominal cavity. The question of retroflexion of the uterus as a cause of abortion was incidentally mentioned. Abdominal section or any severe method of treatment of retroflexion of the gravid uterus was deprecated. Ventrofixation after abortion and involution was recommended in cases of adherent retroflexed uterus.—The PRESIDENT agreed that retention of urine and irritability of the bladder were very important symptoms for diagnostic purposes. Of recent cases, Konrad's, of Budapest was interesting. Relief came too late. Sloughing of the mucous membrane of the bladder and death followed abortion which occurred three days after reduction of the uterus. He had referred at the meeting of the society in April to Unterberger's case, where the displaced pregnant uterus obstructed the bladder and forced open the urachus. Lastly, he dwelt on Gemmell's case at Liverpool, where a woman was seized with abdominal pain and retention of urine at the third month and backward displacement of the gravid uterus was suspected. The mass in the pelvis, however, was found to be a fibroid, which was enucleated through an abdominal incision. The pregnancy continued to term. As to difficulty in keeping the reduced uterus in its place, the President referred to Szanto's case where the displacement was attributed to relaxation of the supports of the uterus caused by typhoid fever; the uterus was replaced manually. Under such circumstances recurrence of the displacement was no doubt very probable.—Dr. J. INGLIS PARSONS had found that the air-ball pessary answered very well. He preferred that gradual method to the more rapid method of manual reposition because it was less likely to produce abortion. Cases of retroversion bound down by adhesions were not at all common; he had never come across a case of this kind in which pregnancy had occurred. If confronted with this complication he would prefer to open the abdomen, free the adhesions, and entertain the hope that the pregnancy would go to term.—Dr. A. L. GALABIN said that he thought that Dr. Sinclair's paper was valuable in calling attention to a mode of treatment the value of which would seem not to have been duly appreciated provided that it proved as successful in the hands of others as in those of Dr. Sinclair. He did not think, however, that this treatment ought to supersede the even simpler one of immediate taxis. He was accustomed to place the patient in the knee-elbow position and apply pressure to the fundus, first from the vagina, then, if that failed, from the rectum. His experience was that an anæsthetic was not required in one case out of 20. He had been accustomed 25 years ago to restore retroversions of the gravid uterus in the out-patient room without even admitting the patients to the hospital. In some cases, however, an anæsthetic alone rendered the taxis practicable. He had never finally failed to reduce a uterus nor had he found it necessary to induce abortion, and for many years he had employed nothing but immediate taxis. His experience therefore strongly confirmed Dr. Sinclair's view that firm adhesions in connexion with retroversions of the gravid uterus were very rare. He had not found abortion follow immediate taxis, but he had known it occur during the use of elastic pressure. He had not employed the watch-spring pessaries as a primary treatment but had always employed them both for keeping up the uterus when restored and in cases in which the restoration at first did not appear to be quite perfect. In future he should certainly try the plan when restoration could not be effected without an anæsthetic. As regarded the mechanism of the pessary he attached even more importance to a leverage which Dr. Sinclair had not mentioned than to the one which he did mention. This resulted from the traction on the cervix produced by stretching backward the posterior vaginal fornix. In this case the uterus itself was the lever, the fulcrum was the position of the internal os, where the uterus was most fixed by its ligaments, and the dragging of the cervix backward tended to tilt the fundus forward.—After some remarks by Dr. HERBERT R. SPENCER, Dr. G. H. DRUMMOND ROBINSON referred to a case of incarcerated, retroverted gravid uterus which he had seen when he was clinical clerk to the late Dr. Matthews Duncan. The patient, who was aged 24 years, was pregnant for the first time. She had retention of urine on Nov. 6th, which was soon followed by constant dribbling of urine. On the 28th nine pints of ammoniacal urine were drawn off by catheter. On Dec. 6th, after many unsuccessful attempts to replace the retroverted gravid uterus, Dr. Duncan induced abortion. On the 5th protrusion and redness of the umbilicus were noticed and a few hours afterwards offensive urine began to ooze from it and this continued until the patient's death on the 20th. The mucous membrane of the bladder began to slough and to be passed per urethram soon after the patient's admission to the hospital. At the post-mortem examination the mucous membrane of the bladder was almost completely absent and the bladder communicated with a fistula at the umbilicus. The uterus was not adherent in Douglas's pouch. The right broad ligment contained an abscess. Dr. Duncan stated that he had never previously been obliged to induce abortion for this condition.—Dr. R. BOXALL thought that they were much indebted to Dr. Sinclair for drawing attention to the fact that abdominal section or any severe method of treatment was rarely called for. For his part, he had never met with a case which would not yield to well-directed pressure and he doubted if anyone present had met with a case which necessitated even puncture before the uterus would be replaced. He regarded chloroform as useful in enabling the reduction to be effected with less force and consequently with less danger of producing abortion than when no anæsthetic was given.—Dr. EWEN J. MACLEAN cited a case of Retroverted Gravid Uterus at the fourth month in a primipara. The symptoms were urgent and, the usual manipulations failing, the patient was admitted into the hospital with a view to the administration of an anæsthetic. After left decubitus, however, for several hours the uterus suddenly reduced itself into its normal position.—Dr. SINCLAIR briefly replied.

Mr. E. RUMLEY DAWSON read a paper on the Essential Factor in the Causation of Sex: a New Theory of Sex. The ovaries, he said, normally discharged ova independently of each other, probably working alternately. The proof was that the number of cicatricial depressions, the result of ruptured Graafian follicles, were nearly equal in each ovary, and together they equalled the number of menstrual periods passed. Normal single pregnancy was the result of the fertilisation of an ovum from one ovary only, by the combined secretion of both testicles; therefore, the male parent did not influence the sex of the coming child. The sex of the child depended upon which ovary supplied the ovum fertilised; if the right a male and if the left a female. He quoted cases of ovariotomy where one ovary only was removed, the subsequent pregnancy giving a child corresponding in sex to the ovary which was not removed. He also gave cases of tubal pregnancy where by operation a male fœtus was removed from the right tube, the corpus luteum being in the right ovary; and *vice versâ* where a female fœtus occupied the left tube, the corpus being in the left ovary. Cases were quoted to show that the affected tube in tubal pregnancy and in tubal moles was generally on the same side as the corpus-luteum-bearing ovary. Cases where either tubal or cornual pregnancy occurred on the opposite side to the corpus-luteum-bearing ovary were unusual and were explained by two theories—viz.: (1) the grasping by the tube of one side of the ovary of the opposite side; and (2) the transmigration of ova. The production of twins and plural births was also considered. Here the ovaries must act at or about the same time when the sex of the twins was different, while when twins were the same sex it was shown that the ovary of one side might provide two ova. Unilateral sterility was shown to account for those cases where the children were all of the same sex or where, after a child of one sex was born, the remainder were of the opposite sex. The usual mixture of children as regards sex which most parents had was due to both ovaries usually being active, and thus supplying children of each sex There were two ovaries only and two sexes only.—The PRESIDENT remarked that discussion on sex problems had been popular from time immemorial, but, however interesting they might be, they seemed ever barren of useful results. Mr. Dawson had taken great pains to collect what must certainly be called clinical evidence and had thus avoided *a priori* arguments founded on one or two cases of unilateral ovariotomy. Did he seriously believe that where a male heir was a matter of national importance the removal of a queen's left ovary would at least avoid disappointment?—Dr G. F. BLACKER was surprised to find Mr. Dawson claiming originality for a thing which dated back to 500 B C. In view of the large number of observations collected by various observers and the numerous experiments carried out upon animals he found it impossible to believe that the male parent played no part in the determination of sex and that the sex of the ovum was settled at the time of its expulsion from the ovary. Mr. Dawson's theory did not explain any of the known facts with regard to the relative proportion of the sexes. Even if they accepted it it did not advance their knowledge as to the real cause of sex. He felt sure that many of the Fellows could instance cases of unilateral ovariotomy and subsequent pregnancy which were in direct opposition to Mr. Dawson's assumption. He could relate two such cases. If the time ever came when they would be able to explain the exact causation of sex he felt sure that it would be found to be, not in one theory or in any one factor, but in a number of factors interacting under varying conditions. Any theory of sex put forward for acceptance must apply to the whole of the vertebrata. Birds had only one ovary. The common fowl had only one, the left ovary. Would Mr. Dawson kindly explain where, according to his view, cocks came from?—After some remarks by Dr. PARSONS and Dr. MAURICE DEE, Dr. SPENCER said that the paper was supported by what appeared at first sight to be an imposing array of facts and contained some statements of opinion which were not facts. It was a pity that more inquiry had not been made as to the sex of the children who were born after unilateral ovariotomy. He had himself removed a left-sided ovarian tumour completely and the patient had in a subsequent pregnancy borne twins of different sexes. There was no doubt whatever that the tumours had been completely removed. Cases of this kind absolutely disproved the theory of Mr. Dawson.—Mr. DAWSON, in his reply, stated that pregnancy, after the removal by operation of the tube of one side and of the ovary of the opposite side, was to be explained by trans-peritoneal migration of the ovum. He did not consider that the male parent had anything to do with sex causation, nor did he consider it necessary to argue from causation of sex in the lower animals, but confined his arguments to the human species. Cases where, for instance, male children were born years after the removal of a right ovary might be explained by a small portion of the right ovary having been left behind, and he quoted two cases to show that this had not infrequently occurred. In one such case both ovaries had been removed, yet a male child was subsequently born on two occasions.

Dr. SPENCER showed two specimens of Parovarian Cyst with Twisted Pedicle, in which the ovary only was congested and inflamed.—These specimens were discussed by the PRESIDENT, Dr. BOXALL, and Dr. MACLEAN.

LIVERPOOL MEDICAL INSTITUTION.

Lupus of the Face.—X-Ray Photograph of an Aneurysm.—Uterine Fibroids.—Peripheral Neuritis.—Medical Weights and Measures.

THE fifth ordinary meeting of the session was held on Dec. 6th, Mr. EDGAR BROWNE, the President, being in the chair.

Mr. C. THURSTAN HOLLAND showed Two Cases of Lupus of the Face treated by x rays. One patient was shown in 1898, and except for a very slight relapse necessitating six more exposures this year had remained cured and was now practically well. The other, a girl, eight years of age, was treated this year for a patch of lupus on the left cheek five inches in diameter. Ten exposures of ten minutes each had resulted in complete cure, the scar tissue being quite soft, non-adherent, and non-contractile—Mr. HOLLAND also showed an x Ray Photograph of an Aneurysm.—Dr. LLEWELLYN MORGAN thought that the case of aneurysm was of interest because the patient had sought relief for hoarseness of the voice rather than for any symptoms directly referred to the aneurysm, and diagnosis was based primarily upon the laryngoscopic examination and pressure symptoms upon the left recurrent laryngeal nerve.—Dr F. H. BARENDT considered the treatment of the cases of lupus to be most satisfactory, and in the case of the girl he thought that the resultant scar was superior to the after-treatment (even when successful) of lupus by scarification, cauterisation, and decorticating medicaments.

Dr. H. BRIGGS read notes of two cases of Uterine Fibroids of Large Size (the growth and uterus weighed 8¼ lb. and 10 lb. respectively). The lower uterine segment was involved and the pelvis was blocked. In cases of this kind the advantage of first getting rid of the growth by enucleation and then of completing the hysterectomy by Baer's method was obvious. In some cases of large tumours enucleation, apparently safe, was tedious or difficult by reason of the dense fibro-myomatous trabeculæ intersecting the tumour and reaching its capsule

Dr. NATHAN RAW briefly described the main clinical features of a recent epidemic of Peripheral Neuritis associated with symptoms of Arsenical Poisoning and showed photographs and lantern slides illustrating the skin lesions and motor paralysis. He described the differential diagnosis between alcoholic neuritis, beri beri, and arsenical poisoning, and gave it as his opinion that the present epidemic was entirely due to the presence of arsenic in beer and stout.—Time did not permit of any discussion on this subject, and the matter being of public importance the discussion was unanimously adjourned to the next meeting, to be held on Dec. 20th.

Brigade-Surgeon-Lieutenant-Colonel E. NICHOLSON read a paper on Medical Weights and Measures. He said that members of the medical profession should form an opinion on the British system of weights and measures and on the alleged superiority of the metric system. He showed the evolution of the imperial weight from the Egyptian royal cubit through the Alexandrian talent and the Roman *libra*, and how the British Pharmacopœia ounce differed by only half a grain from the Roman weight. The history of this and of the rival weights of bygone times, especially Troy weight, was detailed in printed tables. He regretted that the Pharmacopœia Committee had not resisted the permissive use of Troy weight by druggists and showed that the adop- tion of imperial weight in the British Pharmacopœia was ignored by the Board of Trade; he urged the use of "oz." instead of ℥ in the prescription of solid drugs to insure British Pharmacopœia weights being used. An account of the metric system and its fallacies was given; it was being vigorously pushed by advocates whose representation of the alleged irrationality and difficulty of the British system was due to ignorance of it. He pleaded for a better teaching of their weights and measures and of their concordance in schools. If every trade or profession spoke for itself little dissatisfaction would be found with the system which had grown with their civilisation; any trade or any person could decimalise the weights and measures for calculation or industrial purposes. The medical profession were warned against being lured into consent to the metric system by the plausible use of the word "scientific." Examples were given of how the metric system even in France, after more than a century of official pressure and police action, was disliked by the people; they only submitted to the system, without accepting it, and they evaded it whenever possible. The metric system, if made compulsory in this country, would be really a revolutionary system, uprooting a great deal more than their weights and measures.—Dr. KARL GROSSMANN differed from Brigade-Surgeon-Lieutenant-Colonel Nicholson entirely in regard to his conclusions and thought that the paper was an apology for the survival of the system rather than a claim for its persistence. The ancient Egyptians had done many things which they should never attempt and others which the most brilliant intellects had failed to explain, but their mode of measuring and weighing did not suit the present time with its altered conditions of communication as well as the decimal system. The relationship between the metre, the gramme, and the litre was simple and easily intelligible, and the adoption of the metric system would do away with the useless i[illegible]ous of the weights and measures in the old multiplication-table and so far would relieve the brains of their already overburdened school children. The present English system did not show the survival of the fittest but the persistence of the "unfittest," and its proper place was beside the "cubit" in the museum amongst the relics of the past. —The PRESIDENT also made some remarks and Brigade-Surgeon-Lieutenant-Colonel NICHOLSON replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients and Specimens.—Experiences in South Africa.

THE second meeting of this society was held on Dec. 5th, Mr. A. G. MILLER, the President, being in the chair.

Dr. BYROM BRAMWELL exhibited a man showing an exceptional form of Tabes in which the toe reflex was extension instead of flexion. The usual reflex on tickling the sole of the foot was a flexion of the toes, as was first pointed out by a French physician named Babinski some three years ago. In certain conditions of disease in which the pyramidal tracts of the cord are affected, as in spastic paralysis, extension of the great toe resulted. In locomotor ataxia this phenomenon was not present. The case shown was that of a labourer, aged 42 years, who had suffered from tabes for about 10 years. He was markedly ataxic, balanced himself with difficulty, and had trouble with micturition and defecation; there was thoracic analgesia. The knee-jerk was abolished and the Argyll-Robertson sign was present. He walked with his feet wide apart and dragged his legs. On tickling the sole an exception to the ordinary rule was found in that he showed a double extension. The case, however, was not a real exception for the patient had had two attacks of hemiplegia 11 years ago and again two years ago. There was a lesion in his crossed pyramidal tracts as well as tabes dorsalis and this explained the apparent anomaly. The deep reflexes in the upper extremity were feebly marked, but the jaw reflex took the form of a clonus. The lesion had extended up to the cervical region and so had abolished the arm reflexes, but the jaw reflex was still intact.

Dr. MCKENZIE JOHNSTON showed (for Mr. ALEXIS THOMSON) a patient, aged 24 years, after Complete Excision of the Larynx for Epithelioma. In August, 1899, the patient began to suffer from hoarseness, shortness of breath, and dysphagia. These symptoms increased in severity and tracheotomy had to be performed by his own medical attendant on short notice, and later thyrotomy was performed. At this time a piece of the growth was removed and was pronounced by Professor W. S. Greenfield to be a malignant papilloma. On examination on Oct. 4th the whole larynx was found to be filled with a fungoid mass which pressed on the epiglottis. A further thyrotomy was done as the growth did not appear to be malignant, as much pus escaped, and the cartilages were found to be bare. After a week's delay, and on the pathologist's report that it was a squamous-celled epithelioma, the whole larynx was removed. The patient was in excellent condition both before and after the operation, and the remarkable fact was his early age. His power of speech was feeble but distinct. Part of the anterior pharyngeal wall was removed at the same time. The patient was out of bed a week after the operation and in three weeks was able to swallow anything.

Mr. HAROLD STILES showed: 1. A boy, aged six years, after Excision of a large Simple Lymphoma of the Neck. The glands had been enlarging for two years and at the operation they extended from below the jaw to the clavicle as a large lobulated mass. The interest lay in the size of the growth and in its pathology. Many surgeons thought that it was a multiple cystic hygroma, but Mr. Stiles thought it was glandular because it had a doughy, false fluctuating feeling, as if a bunch of grapes were under the skin. The operation was not difficult as the glands were not adherent. The spinal accessory nerve went through the mass and had to be sacrificed. There was no recurrence in the region of the operation but there were one or two enlarged glands in the parotid region. The glands on section had a sarcomatous appearance, but they had really undergone a simple hypertrophy. Such glands must be developed after birth and they might result from a change of the fat cells into lymphoid tissue. 2. A girl, aged eight years, six months after Amputation at the Hip and the removal of the greater part of the innominate bone for tuberculosis. Previously to this major operation she had been subjected to several operations for the removal of tuberculous disease. The disease, however, recurred in the hip, and as the patient was dying from hectic this operation was performed. A skiagram taken six months after the operation by Dr. H. Rainy showed that re-formation of some bone had taken place. The liver, which was enlarged and waxy, had also undergone diminution in size.

Dr. GEORGE ELDER exhibited (1) four Brains showing four different Seats of Cerebral Hæmorrhage, and briefly described the clinical history of each; and (2) a Tumour of the Dorsal Vertebræ pressing on the Spinal Cord from a case of paraplegia.

Dr. BYROM BRAMWELL showed: 1. A Horizontal Section through the Brain with a large Tumour of the Motor Centres and Centrum Ovale (infiltrating glioma). The specimen was from a man, aged 24 years, who had had frequent attacks of Jacksonian epilepsy, beginning in the left hand and on the left side of the face. He had no other general symptoms of cerebral tumour. Under iodide of potassium and bromide of potassium he improved, but returned later with the same attacks and some loss of power in the arm and leg. The diagnosis was a small glioma in the motor area. Mr. J. M. Cotterill trephined over the face centre, but the brain appeared to be normal. Faradaisation over the motor area failed to produce muscular contraction even with strong currents. The patient soon recovered from this operation and was discharged. Later he returned with left-sided hemiplegia, double optic neuritis, and hernia cerebri. His headache suddenly became very severe and he died. The points to note were that there may be a brain tumour with merely localising symptoms but no general symptoms, and that faradaisation may fail to cause muscular contraction. 2. A Skull-cap from a patient who died three months after the operation of Trephining in a case of Cerebral Tumour.

Professor J. CHIENE, in bringing before the society his paper on Experiences in South Africa, said that he had divided the account of his stay in South Africa into two periods—viz., the period from the beginning of April until the end of June, and the period from the end of June until the end of August; from Cape Town to Norval's Pont in the first instance and from Norval's Pont back to Cape Town in the second. Whatever might be the verdict of the Hospitals Commission everyone must allow that the question of army medical reform was only a sub-section of the wider question of army reform. The four great hospitals in the neighbourhood of Cape Town were Wynberg No. 1, Wynberg No. 2, Rondebosch No. 3, and Woodstock No. 4. Much had been said about Woodstock. It was an old building near Cape Town, lying on the shore, and, like all old buildings in South Africa, it was infected with animal parasites at one time. On his second visit great improvement in this particular had taken place. He never noticed any smell from the town drains which opened into the bay near the hospital. The drain for sewerage opened 300 yards from the shore and the current carried the dejecta away from the hospital, and, judging from the excellent results of the surgical cases which he saw there, he could not look upon the hospital as an unhealthy one. The dejecta from the hospital, after being mixed with izal, were buried in a trench on the shore. Professor Chiene's time was principally spent in the Wynberg and Rondebosch hospitals and both hospitals were on excellent sites. Regarding the conveyance of the soldiers from the trains and the hospitals, he said that being at Wynberg he saw them arrive by train and again saw them immediately after admission to the hospital. The difference between hospital trains and ordinary trains carrying invalids must be clearly understood. In the former the soldiers were most comfortable, while in the latter the reverse was often true. In future, Professor Chiene urged, some form of portable cooking stove must be carried in these ordinary trains by means of which simple food may be cooked. A supply of food at the stopping places could not be depended upon. It was often very sad to see how worn and weary the poor fellows were on their arrival. As regards their conveyance from the trains to the hospital at Wynberg, this was done in ambulance carts. On a smooth road such a cart was fairly comfortable, but in his opinion the ambulance litters were certainly more comfortable, and he thought it would be a question for the future if these litters should not replace carts in the conveyance of patients from trains to hospitals. These litters were on rickshaw wheels with rubber tyres and they worked most smoothly. A question for the future would also be, Could any improvement be made in ambulance wagons for the removal of patients from the battlefield to the nearest hospital? The Boers used, as a rule, wagonettes and Cape carts. The essentials of such an ambulance wagon were strength, easy turning, easy motion, and easy access to the patient by the attendant. The stage coaches in South Africa were hung on leather, but in ambulance carts care would be necessary to prevent too great a swing of the carriage for fear of sickness which was analogous to sea-sickness. Professor Chiene then stated his experience under the following headings: 1. Anæsthesia.—Chloroform was the favourite anæsthetic, but he had never seen any trouble with any anæsthetic and very little subsequent sickness. The condition of the wounded soldier reminded him of the state of a patient suffering from shock, not taking much interest in his own case, and this long after the receipt of his injuries (for these cases were seen at the base). They seemed to be suffering from "chronic shock," if the term might be used. He could recall only one case of a soldier who refused to be operated upon. 2. X rays.—Great difficulty was often experienced in localising bullets in the spine and pelvis, but in the limbs little difficulty arose. In the pelvis a rectal examination would sometimes localise a bullet when the x rays had been found wanting. He was satisfied that the efficient use of the x ray apparatus depended very much on the experience of the man who used it. The method of McKenzie Davidson gained most acceptance. 3 Hospital trains and ships.—In Natal the absence of corridor carriages rendered the Princess Christian's hospital train of much value, and fortunately it was ready just in time to cross the Tugela after the relief of Ladysmith. In Cape Colony there were four trains with every comfort. The good that these trains did was incalculable. Kipling had written about them and Professor Chiene wished that his article might be reprinted separately. As regards hospital ships, he had no experience of those fitted up at home, but he saw two of the sick ships fitted up in Durban, the *Lismore Castle* and the *Simla*, and nothing could be better, with every comfort and convenience. Colonel Gallwey looked upon these ships as base hospitals. They contained 1660 beds. It had to be remembered that the problem in Natal was a much easier one than was that in Cape Colony—50,000 men as compared with 150,000; 200 miles of railway as compared with 1000. 4. Bullet wounds.—When a soldier was struck at near range the wound was worse than when the charge was received from a distance. When struck at a distance of between 200 and 400 yards a more ragged wound resulted than when struck at 1000 or 1500 yards. Possibly the bullet was like a top, at first it spun round a centre and then after a time settled down into its true course. The cases of severe brain injury must be divided into two groups: first, those in which the bone and brain were severely injured and torn; and, secondly, those in which, with a comparatively small bone wound, the brain was much torn. In the first the injury was probably due to expanding or explosive bullets; in the second the Mauser bullet might be the cause when fired at short range. Dr. Hugh Marshall had examined the green coating of some bullets and had found that it was due merely to the action of fatty acids on the copper. 5. Head injuries.—The cases of cerebral hernia which Professor Chiene saw in South Africa seemed generally to be on a fair way to recovery, and in some this was complete. Dr. Louis Irvine, a civil surgeon at Port Napier, Pietermaritzburg, spoke of the good results of formalin in cases of hernia cerebri. Professor Chiene saw several cases of severe brain injury followed by recovery. He related several remarkable cases of such injury in which recovery took place. 6. Injuries of blood-vessels.—He had seen several cases of arterio-venous aneurysm. They occurred in the neck and in the extremities. Much improvement resulted from proximal ligature of the main artery when the communication was between the carotid artery and the internal jugular vein. In the thigh ligature of the femoral artery did good and in the leg the aneurysm was generally laid open and the artery and vein were ligatured above and below the opening. The improvement which took place after proximal ligature of the main artery with the absence of any venous dilatation made him wonder if the condition could be due to bruising of the artery and vein and subsequent matting with constriction. The number of cases of painful neuritis from bruising of the nerve, those due to adhesion of the nerve to bone after fracture, and those due to splinters of bullets lodging in the nerve made him think that the same might have occurred to arteries and veins lying side by side. 7. Injuries of the thorax.—It was exceedingly rare to find a patient who said that he had spat blood at the time of the wound to the lung. Apparently the Mauser and Lee-Metford bullet passed through the lung searing it and preventing hæmorrhage. On the other hand, in many cases there was hæmothorax, probably from the intercostal vessels. Empyema as a result of lung injury rarely occurred and he saw only four cases. He had seen several cases of penetrating thoracic wounds in which after careful examination of the entrance and exit wounds he could not but conclude that the bullet had traversed the heart. 8. Abdominal injuries.—He had no opportunity of forming an opinion on the question of immediate operation in penetrating wounds of the abdomen. It was currently believed that the hungrier a man was the less was his risk in an abdominal wound. As in the lung, so in the intestine, apparently the Mauser bullet made so small a wound that neither bleeding nor extravasation occurred. He could explain the recoveries after penetrating wounds in no other way. In speaking of enteric fever Professor Chiene said that hospital huts and tents were better than houses in which to place the patients. He with many others looked with apprehension to the coming year for fear of an outbreak of enteric fever and especially amongst the new immigrants. The dejecta of typhoid and dysenteric patients had been thrown out all along the railway lines. He thought that there should be no delay in sending out the best incinerators and compelling the authorities to burn the dejecta. There was much difference of opinion as to the merits of typhoid inoculation. Many thought that what was called in the army "simple continued fever" was aborted typhoid fever and at Estcourt Hospital he was informed that five out of six such cases reacted to the Widal test. Had these patients been inoculated for typhoid fever and was the reaction due to the inoculation? The Widal test was not in use, as a rule, in the military hospitals and it was from the civil hospitals that its value as a diagnostic would be heard of. As regarded dysentery he was struck with the general depression of spirits of the patients. The treatment by the free use of magnesium sulphate followed by ipecacuanha was the favourite remedy. In conclusion, Professor Chiene expressed the hope that the medical history of this war would be fully described in the form and with the thoroughness that the great Civil War in America had been dealt with by the Government of the United States. From such a history many most valuable lessons would be learnt which would be of the greatest use to all members of the medical profession, but especially to the members of the Royal Army Medical Corps, and to those civil surgeons who in the future might be called upon to serve Her Majesty in times of war.

Dr. ROBERT STIRLING (Perth) also very briefly described some of his experiences as a surgeon in South Africa.

Society of Medical Officers of Health.—A meeting of this society was held on Nov. 9th, Dr. A. Newsholme, the President, being in the chair.—Mr. J. Cantlie read a paper on Plague, its Symptoms and Spread, in which he insisted on the insidious character of the disease at the commencement of an outbreak, the early cases being, as a rule, difficult of diagnosis and appearing for the most part as a non-fatal bubonic fever. Thus in 1893, the year preceding the virulent epidemic at Hong-Kong, numerous cases of non-syphilitic buboes were operated on among the seamen of the British Navy, and the same thing had been observed elsewhere. It was important to distinguish between these cases, which he called cases of "pestis minor," and the mild cases occurring during an epidemic of the typical and virulent disease, to which he would give the name of "pestis ambulans." All the cases of pestis minor that he had seen were among seamen. After a few days of febrile disturbance a gland in the groin became swollen, pus escaped through openings in the skin, and on cutting down the gland was found to be suppurating and separated from its surroundings except at one point. The treatment consisted in excision of the gland with perhaps *those in the vicinity that were at all inflamed and packing* with iodoform gauze. The wound usually healed in three weeks, and by the end of the month the patient was convalescent. In the true or virulent type of plague the suddenness of the fatal termination was most striking. When he first took charge of the plague hospital at Hong-Kong he was surprised to see the patients sitting up, talking, and smoking, some eating and a few sleeping, but still more so to find that during his round of 20 minutes four of the 25 patients in the ward had died, as did the whole of his first 50 patients within a few days. After discussing the incubation period, the mode of invasion, and the chief types he said that bubonic cases constituted 70 per cent. of the whole number, but that the septicæmic cases (in which there were no buboes though the whole of the glands were enlarged) and the pneumonic cases (in which they were unaffected, the lungs alone being manifestly involved) were far the more fatal. Mr. Cantlie described fully and in order the signs and symptoms common to all cases, which at first and apart from those connected with the lymphatic system were not characteristic, being such as were met with in all fevers of a severe or malignant type. Vomiting if persisting beyond the third day was an unfavourable sign. The vomit might have a coffee ground appearance, not, however, indicative of hæmatemesis, though blood occasionally appeared in the stools. Diarrhœa was almost always present, but might be preceded by constipation. The enlargement of the spleen was very marked, often to the extent of three or four times its natural size, but that of the liver was less evident. The right heart was usually dilated, the apex beat was diffused, the sounds were short and feeble, a præcordial thrill was felt, and perhaps a systolic murmur was audible. In bubonic cases there were rarely any pulmonary symptoms, at any rate, prior to the fourth or fifth day, or till immediately before death. The urine was scanty and acid, typically febrile, but blood might be present, and albumin was frequently present in some epidemics though absent in others. Apathy and listlessness were the rule, but there might be delirium or sleeplessness or even a tendency to a purposeless wandering from the bed and perhaps from the house. Petechiæ and extensive subcutaneous hæmorrhages with sloughing of the skin over the buboes were frequent, but boils were rare, and so was a rash which, when present, resembled that of typhus. The poison of the plague seemed to expend its action especially on the lymphatic system. There might be only a single bubo, but the glands might be enlarged throughout the body. On the other hand, buboes might be numerous, those in the axilla and neck being attended by much œdema, even so great as to press on the larynx. Axillary and cervical buboes were very grave symptoms. The enlarged glands were always tender and might be extremely painful In the septicæmic form the prostration was extreme, with delirium passing into coma, hyperpyrexia, and other symptoms of intense toxæmia, and general enlargement of the glands, though no buboes were formed. In the pneumonic form the glands were in no way affected, but the lungs showed irregular patches of consolidation with frothy mucous expectoration frequently stained with blood. A bacteriological examination of the sputa revealed the true nature of what could not otherwise be distinguished from a severe catarrhal pneumonia. In all cases of plague the fever ran high, but the typical curve showed a double rise with an intervening fall to, or near, the normal on the third and fourth days. It was usually fatal on the fifth and sixth days, but might be so within 24 hours, or death might be delayed till the tenth or even the twelfth days. The diagnosis of a typical bubonic case was easy, but in the absence or before the appearance of these lesions certainty could only be attained by a bacteriological examination, especially in tropical countries where malarial, filarial, and relapsing fevers of severe types were met with. The plague was less fatal to Europeans than to Asiatics, and most so to the Mongolian race. Among Europeans in India and in the epidemic at Sydney it was from 30 *to* 40 per *cent*., among Hindoos *from* 60 *to* 70 per cent., and among Chinese from 85 to 95 per cent., or even higher. The prognosis in individual cases was well-nigh impossible, apparently mild cases often ending fatally and hopeless ones occasionally recovering. The worst symptoms were sleeplessness, delirium, coma, persistent vomiting or diarrhœa, renal or intestinal hæmorrhages, petechiæ, *extravasations*, and *cervical or multiple* buboes, while the septicæmic and pneumonic forms were very fatal. A return of the fever after the second fall, or the tenth day, was indicative of pyæmia and of fatal significance, whereas if a patient lived to the tenth day, was clear in intellect, and free from actively suppurating buboes his recovery might fairly be expected.

Glasgow Obstetrical and Gynæcological Society.—A meeting of this society was held on Nov. 28th.—Dr. Robert Jardine, the President, delivered an address on the Glasgow Maternity Hospital, Past and Present. He gave an account of the midwifery work carried on in Glasgow before the first maternity hospital was started. In the sixteenth and seventeenth centuries the work was largely in the hands of midwives. In those early days the Kirk looked after the morals of the midwives. From Dr. Duncan's Memorials of the Faculty of Physicians and Surgeons of Glasgow he quoted that one Kate Freeland was summoned before the Presbytery on April 4th, 1589, "to assr. for her professioun to be ane midwyfe qlk has not been knawin win ye toun and citie of Glasgow to ye inhabitatis yair, and to underly ye (censure ?) of ye Kirk according to her demerites." Dr. Jardine then pointed out that in 1740 the faculty had instituted an examination for midwives which was continued throughout the century. It was enacted that "after the 1st of January, 1741, any midwife who shall pretend as such to practise within the shyres of Lanark, Renfrew, Ayr, and Dumbarton without a licence shall be fined in the sum of forty pounds." Two-and-sixpence was the only charge made for the licence. It would thus be seen that the registration of midwives which has become such a burning question south of the Tweed was no new thing in Scotland. The first maternity hospital of which records could be found was a small private one started in 1791 by James Towers, surgeon. Mr. Towers afterwards became the first Professor of Midwifery in the University in 1815. In 1805 an attempt was made to found a public lying-in hospital, but it failed. In 1834 the Glasgow Lying in Hospital and Dispensary was founded by Dr. James Wilson. Dr. Jardine described the progress of this hospital and showed how it was being hampered for want of funds and by unsuitable accommodation. Epidemics of puerperal fever were common, but in spite of opposition the hospital struggled on until at length the present building was opened in 1881. He pointed out that the present hospital, although it might have been quite up-to-date 20 years ago, was now far from an ideal place in which to do the work which they were called on to perform. Not only was it too small, but there was neither an operating theatre nor an isolation ward in it, and the labour rooms were no larger than ordinary bedrooms. The operative work, he pointed out, had increased tremendously, quite tenfold, especially within the last decade. From 1834 to 1841, in the first hospital, 445 cases were treated. Of these, six were forceps cases (one in 74), two were cases of version (one in 222), and one was a craniotomy case (one in 445)—nine operations in all; while during the 10 years from 1889 to 1898 inclusive there were 4322 cases: forceps 650 (one in seven), version 154 (one in 28), craniotomies 112 (one in 39), inductions of labour 90 (one in 48), Cæsarean sections 56 (one in 77), post-mortem Cæsarean sections two (one in 2161)—1064 operations in all (one in four). In conclusion Dr. Jardine made a strong appeal to the Fellows of the society to make known the wants of the institution and he felt confident that if they did so and if the public realised that the work was hampered for the want of proper accommodation funds would soon be provided for a hospital worthy of the great city of Glasgow. He closed his address with a short history of the different men who had held the appointment of chief physician in the past. The founder, Dr. James Wilson, and his son, Dr. J. G. Wilson, had been on the staff for nearly 50 years. Dr. Jardine also showed to the society a large number of interesting specimens and also all the newest instruments and apparatus employed in midwifery work.—On the motion of Dr. W. L. Reid a hearty vote of thanks was accorded to Dr. Jardine for his interesting address.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At the annual meeting of this society held on Dec. 3rd, Sir William Dalby, the President, being in the chair, certain alterations were made in the existing rules of the society. The election of office-bearers for the ensuing year then took place.—Mr. A. H. Cheatle showed a patient suffering from Deafness, Perversion of Taste, and Facial Paralysis associated with Herpes.—Dr. W. Milligan considered the case to be one of peripheral neuritis probably of post-influenzal origin.—Mr. C. A. Ballance concurred with this expression of opinion.—Mr. C. H. Fagge showed a patient suffering from Bilateral Auditory Nerve Paralysis and suggested the diagnosis of intracranial tumour.—Mr. Cheatle asked as to the characteristics of the vertigo from which the patient suffered.—Dr. Milligan asked whether puncture of the lumbar theca had been performed and the fluid analysed. He considered that the symptoms, as detailed, did not warrant the diagnosis of intracranial tumour, but pointed rather to the existence of a chronic basic meningitis, possibly of syphilitic origin.—Mr. Fagge, in reply, said that no lumbar puncture had been performed and added that no history of either congenital or acquired syphilis could be ascertained—Mr. Richard Lake showed a patient upon whom a Double Ossiculectomy for Chronic Suppurative Middle-ear Disease had been performed.—Mr. Cheatle asked how long the discharge had lasted and what was the original cause of the disease.—The President remarked that it was not always possible to foretell what the condition of the hearing power would be after the removal of the ossicles. The case shown appeared to be very satisfactory.—Mr. G. W. Hill asked whether Mr. Lake only practised ossiculectomy or whether he also curetted the attic, also whether Mr. Lake removed the outer wall of the attic under a general anæsthetic.—Dr. A. Bronner suggested the frequent insufflation of iodoform powder in such cases.—Mr. Fagge asked whether operation had been performed under local anæsthesia.—Dr. Milligan inquired as to whether any preliminary antiseptic treatment had been adopted.—Mr. W. O. Bull said that the case was not an instance of pure ossiculectomy, as in this particular case the outer wall of the attic had also been removed.—Mr. Lake, in reply, said that the discharge had lasted for 30 years and that the original cause was scarlet fever. In such cases he not only removed the outer attic wall but also curetted everything which he could. Preliminary antiseptic treatment had been tried for three months.—Mr. Herbert Tilley showed a patient upon whom the mastoid operation had been completed by multiple epithelial grafts.—Mr. Ballance pointed out that the patient could hardly be regarded as completely cured, as a considerable perforation still existed in the situation of the original membrane and as discharge was still present. He did not think that either tympanum or attic had taken the graft, as should be the case. He also considered it essential that all soft parts should be removed from the tympanum at the first operation in order to secure subsequent successful grafting.—Mr. F. C. Abbott related the history of a patient suffering from Primary Sarcoma of the Base of the Skull in the position of the Eustachian tube.—Mr. Ballance and Dr. Milligan demonstrated a new Portable Motor for surgical purposes especially designed for operation on the mastoid region. The motor was of about one-twelfth horse-power and ran quietly and steadily. The speed was regulated by a foot arrangement. The burr was attached to a steel flexible arm which enabled it to be used at a considerable distance from the motor. The hand-piece was detachable and in construction was simple, and was made so as to enable it to be thoroughly boiled for disinfection purposes.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in the library of the Medical School, Leopold-street, Sheffield, on Nov. 16th, Dr. J. B. Hellier, the President, being in the chair.—The following specimens were shown:—Dr. J. W. Martin: Pyosalpinx removed by Abdominal Section.—Mr. Richard Favell: (1) A Ruptured Fallopian Tube from a case of Ectopic Gestation; (2) Double Pyosalpinx; and (3) Cast of Bladder from a case of Exfoliative Cystitis.—Mr. S. Rumboll: Epithelioma of the Clitoris.—Dr. Martin related a case of Acute Inversion of the Uterus in a primipara which had occurred spontaneously an hour after normal labour and was accompanied by great pain, hæmorrhage, and shock. Under chloroform 10 hours later the uterus was completely reduced by taxis, though not without considerable difficulty. The patient made an uneventful recovery.—Dr. T. B. Grimsdale related a case of Vesico-vaginal Fistula with Destruction of the Posterior Wall of the Bladder and Urethra which had occurred as the result of sloughing after labour in a primipara, aged 21 years, with contracted pelvis. A simple cloaca existed between the bladder and the vagina and the urethra had entirely disappeared. In the treatment two objects were to be obtained: (1) closure of the bladder, and (2) restoration of control over the urine. The bladder was first dissected away from the uterus up to the peritoneal reflexion. This fold was then brought down which materially reduced the size of the opening. At a later period the uterus was pulled down and fixed to the perineal muscles, so that by their contraction the cervix could be pressed against the symphysis and pubic arch, forming an obstruction to the escape of urine. The patient was now quite dry if she kept quiet, but urine escaped on exertion to any extent. No trace of urethra could be discovered. Dr. Grimsdale wished to elicit the views of members with regard to future treatment.—Remarks upon the case were made by Dr. W. J. Sinclair and Dr. A. Donald.—Dr. Hellier read a note on the Occurrence of Abortion. He had analysed the histories of 1800 married women who were out-patients at the Hospital for Women and Children at Leeds. These women had given birth to 6974 children, an average of 3·87 children each. They had had 1288 abortions—that is, one to every five and a half children. 1616 of the women had become pregnant; 184 were sterile. Of the 1616 58 only had had one or more abortions, but had never gone to term. Thus it followed that amongst a group of women in whom the frequency of abortion might be supposed to reach its maximum 96·5 per cent. of those who became pregnant, sooner or later, bore one or more children at term.—Dr. Sinclair read a paper on a Series of 10 Successful Cases of Cæsarean Section.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 5th, Dr. T. C. Railton, the President, being in the chair.—Mr. E. Stanmore Bishop showed a patient from whom an Adenoma of the Sigmoid Flexure with the Intussusceptum which it had produced had been removed by Maunsell's operation after a preliminary colotomy. He remarked that the condition itself was not very rare, but that operators frequently attacked it through the dilated rectum. This was practicable enough if the growth was well within reach, but there were two definite risks in this method which became greater the higher the situation of the neoplasm. One was the possibility during the reduction of the reunited intestine—if the intussusceptum regained removal—of the tearing out or giving way of one of the sutures, which, when once the bowel had regained its normal position, would be out of range of either sight or touch, and septic peritonitis might be set up without much or any warning. Another was the necessity for fæcal matters to pass over the wound during the period of reunion and the consequent possibility of septic absorption. Both these risks were avoided by a preliminary colotomy which permitted a perfectly aseptic operation upon the bowel itself, whilst Maunsell's operation which he described gave a more perfect means of excision and reunion of the intussuscepted gut. The patient, specimen, and a microscopical section of the growth were shown.—Dr. R. T. Williamson briefly described a case of Melanotic Sarcoma of the Liver following a primary growth in the right eye. The patient was 16 years of age. The liver was uniformly enlarged and it extended from the fourth rib to the anterior iliac spine on the right side; there was no ascites. The urine gave the reactions for melanin. At the necropsy the liver weighed 13¼ pounds and was infiltrated with melanotic sarcoma at all parts. The kidneys and other abdominal and thoracic organs were unaffected. Remarks were added on the diagnosis of melanotic tumours of the internal organs and two other cases (previously recorded) were referred to.—Mr. J. W. Smith read a paper on Clinical Experiences in South Africa which was illustrated by lantern photographs of a military hospital.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on Nov. 29th, Dr. William Watson, the President, being in the chair.—Dr. Ebenezer Duncan showed: (1) A case of Spinal Apoplexy; (2) a case of Acute Nephritis which had developed uræmic convulsions treated with benefit by blood-letting; (3) two Cardiac Cases with well-marked murmurs and no history of any previous rheumatic affection; (4) a case of Phthisis Pulmonalis in a soldier in whom the disease had developed in South Africa; and (5) a case of Diabetes Mellitus. In this patient benefit had been observed following the use of nitrate of uranium.—Dr. Alexander Napier showed: (1) A number of cases of Lupus Vulgaris in which very good results had been obtained by curetting and then cauterisation with the thermo-cautery; (2) a case of Jacksonian Epilepsy in a girl; (3) a case of Hemicrania in a boy; he read (4) a description of a fatal case of Glioma of the Brain; and further showed (5) a case of Peripheral Neuritis; (6) a case of Arthritis in a girl, running a rapid course; (7) several well-marked examples of Graves's Disease —in some the kidneys were freely moveable; and (8) some cases of Diabetes treated with Nitrate of Uranium.

Reviews and Notices of Books.

Indian and Colonial Addendum to the British Pharmacopœia, 1898. London: Printed and published for the Medical Council by Spottiswoode and Co. 1900. Pp. 59.

FOR many years it has been obvious that, whatever merits the British Pharmacopœia possessed, some of the preparations were not of universal applicability. Some would not bear exportation to India and the colonies, others which might be prepared locally would not yield satisfaction if compounded in strict accordance with the directions given in the British Pharmacopœia, and many could not with advantage be so prepared owing to the difficulty of obtaining some of the ingredients. Moreover, it was frequently felt that there were many local drugs which were used with greater facility, and although they could not be termed substitutes, since they did not possess precisely the same properties, yet in many of their more important actions they corresponded closely with drugs recommended for employment in Great Britain and Ireland. Although, therefore, in general the British Pharmacopœia could be followed in India and the colonies, there were many exceptions which indicated the need of some modifications for local requirements before the Pharmacopœia could be regarded as an authority, a standard, and a guide throughout the British empire.

In 1898 official recognition was extended to a small number of alternative substances and preparations, but many suggestions received from Indian and colonial authorities were held over for further investigation. The small volume at present under consideration is stated in the preface to be to a certain extent provisional. It is the first step in a new direction, and therefore it is introduced with becoming modesty, and it is frankly admitted that with regard to the sources, preparations, and properties of some of these drugs further research, especially in the countries in which they are found, is much to be desired.

The Indian and Colonial Addendum to the British Pharmacopœia, 1898, contains 54 drugs and 66 preparations. The names of eight or ten of the former are familiar; they are representatives of former pharmacopœias which still have a local reputation outside the British Isles and it is quite possible, or even probable, that in the fresh condition they may possess properties which they lose when dried for transportation. The remainder of the drugs present us with new names, and it is interesting to see that the divisions of the empire within which each new drug now acquires official sanction are indicated. It is, perhaps, natural that numerically tinctures head the list of the new official preparations; there are, however, representatives of most groups with the exception of suppositories. Considering that the British Pharmacopœia, 1898, contains only three decoctions, it is somewhat remarkable to find no less than seven included in the Addendum. These can, of course, be only intended for local employment, but possibly some of the group of liquid extracts will find their way to this country and may be destined to play an important part; the liquid extract of bael will probably be welcomed by many practitioners, since the exclusion of bael from the British Pharmacopœia has often been regretted. It will be noted that bael is only official in the fresh state and that the liquid extract is prepared from the fresh half-ripe fruit, it can therefore be relied upon to produce results analogous to those observed in India. The influence of the last revision of the Pharmacopœia is further shown in the presence of several concentrated liquors, the relatively new process by which the time and labour of the dispenser have been saved. Those responsible for this compilation have been careful to follow the British Pharmacopœia in dosage, most of the official preparations having been prepared so as to permit of great harmony of dose.

The primary idea of this Addendum is to produce a standard authority adapted to Indian and colonial requirements, and it may be interesting to indicate some of the directions in which these remedies may be employed in the special places in which they now become official. In their actions and properties many of the plants are regarded as the local equivalents of drugs which are, or have been, official in the British Pharmacopœia, but it is, however, distinctly laid down that, with some few exceptions, they are not to be substituted by the dispenser or pharmacist; they must be prescribed by the medical practitioner on his own judgment. The list includes several astringents, some of the preparations being intended for local application—for example, acacia bark in place of oak bark (which is no longer official), butea gum in place of kino, black catechu in place of the official pale variety, myrobalans in place of galls, and sappan instead of logwood. The re-introduction of bael fruit, which possesses a great reputation for the treatment of diarrhœa and dysentery, has already been mentioned. The purgatives are relatively few, the chief being kaladana and turpeth, which resemble jalap in their action, and Indian podophyllum derived from Podophyllum Emodi. The anthelmintics include butea seeds which are used as the equivalent of santonin, and embelia which possesses some of the properties of kousso and of male fern. Although the bitter oil of the seeds of Indian azadirach is much used in India as an anthelmintic, the bark and the preparations owe their position in the Addendum to their tonic and antiperiodic properties, which have sometimes been considered to equal those of cinchona and arsenic. Other tonic remedies which are reported to possess antiperiodic properties are alstonia and tinospora; the latter, however, probably only acts as a bitter tonic like calumba, and the same may be said of coscinium; toddalia is thought to be the Indian representative of cusparia and andrographis that of chiretta. In the possession of emetic, diaphoretic and expectorant properties tylophora leaves have been ranked with ipecacuanha, and calotropis appears only to differ from the same drug in having greater action as an alterative. Cotton-root bark, which now becomes official over a very extended area, has been used largely in place of ergot. Grindelia and kava may be employed as anti-spasmodics, diuretics, and expectorants, while viburnum is not only an anti-spasmodic but also an astringent and a diuretic. One of the most important additions is the recognition of mylabris, a dried beetle which is now official in India, in the African, and in the Eastern colonies. Mylabris yields a large proportion of cantharidin, and it will be noted that the new official preparations closely correspond with those in the British Pharmacopœia derived from cantharides.

In the foregoing notice we have only touched upon the more striking features of this Addendum, in which it will be obvious that a difficult task has been approached with caution and with tact. Doubtless many of the formulæ will require further adjustment before they are wholly satisfactory, but it is to be hoped that this will be effected by modifications of composition rather than by alteration of dose Nothing has been said of the very full descriptions of the botanical characters; so far as it is possible to test these they appear to be extremely well done. Many of the descriptions, however, apply to fresh specimens and as the specimens of the dried plants sent to England often differ widely in character it will, perhaps, be safer to leave this subject to Indian and colonial criticism.

LIST OF SUBSTANCES AND PREPARATIONS IN THE INDIAN AND COLONIAL ADDENDUM TO THE BRITISH PHARMACOPŒIA, 1898.

Acaciæ Cortex
Acalypha
Acetum Mylabridis
Acetum Urgineæ
Adhatoda
Agropyrum
Alstonia
Andrographis
Aristolochia
Arnicæ Flores
Aurantii Cortex Indicus
Azadirachta Indica

Belæ Fructus
Berberis

Tinctura Tinosporæ
Tinctura Urgineæ
Tinctura Valerianæ Indicæ Ammoniata
Tinospora
Toddalia
Turpethum
Tylophoræ Folia

Unguentum Gynocardiæ
Unguentum Mylabridis
Unguentum Myrobalani
Unguentum Myrobalani cum Opio
Urginea

Valerianæ Indicæ Rhizoma
Viburnum

Defects in Plumbing and Drainage Work. By FRANCIS VACHER, Medical Officer of Health of Cheshire. London and Manchester: John Heywood. 1900. 8vo Price 1s net.

IN all technical subjects the student has to acquire not only an exact knowledge of what to do, but also what it is desirable to avoid doing, and the book before us deals with this aspect of the plumbing question. The book is an enlarged edition of a work published some 10 or 11 years since, and describes various defects in plumbing and drainage work which came under the author's notice in his professional capacity since 1885, and is now brought up to the present time The book is augmented with over 100 illustrations, but the bulk of the defects was chronicled in the first edition. The whole forms a most depressing record; in fact, it is in the nature of a gallery of horrors, which we would fain hope are rapidly being relegated to the limbo of ancient history. These defects may be mainly classed under four heads—viz, (1) defective planning of the sanitary system, arising from ignorance or total disregard of sanitary laws; (2) from practical incompetence on the part of the operative, leading to faulty pipe-joints and bad work generally; (3) from the sanitary appliances used being either faulty in design or construction; and (4) from a combination of two or more of the above.

The author points out that these defects have a tendency to repetition, yet we cannot but cherish the hope that the improvement in local by-laws and in the machinery for their administration, together with the great advance made in technical and general education both by the sanitary inspector and the operative plumber, will render any frequent repetition of the worst form of these horrors impossible. That this is so in the vicinity of London we feel sure, though in numbers of the older houses scattered throughout the country such defects are frequently to be found The defects due to ignorance will doubtless disappear, though the process of evolution may be slow. With those due to disregard of sanitary laws it is different. The demand for cheapness, combined with cupidity on the part of those who cater to satisfy this demand, leads to systematic deception most difficult to combat, and some form of legislation to render those responsible for such fraudulent acts amenable to the law would seem to be desirable

The book is to be commended as emphasising the enormous importance of the careful supervision of all such work and the great responsibility that rests upon those deputed to act as supervisors, whose posts are frequently inadequately remunerated, thus failing to secure the services of the best qualified men.

CHRISTMAS BOOKS.

MESSRS. BLACKIE AND SON send us (1) *With Rifle and Bayonet.* By Captain F. S Brereton, R A.M.C. With eight Illustrations by Wal Paget 1901 Pp 352 Price 5s. Captain Brereton, who is now at the front, has found time among very arduous labours to write an admirable book. The story deals with the events of the Boer War up to the occupation of Bloemfontein, and Jack Somerton, the hero, certainly does his share of fighting Captain Brereton's style is easy and vivid and the book is an excellent present for a boy. (2) *In Far Bolivia* By Gordon Stables, M.D, C.M. Aberd., R N. With six Illustrations by J. Finnemore, R.I. Pp 287. Price 3s 6d. The author takes his reader, to that little known land, Bolivia The story would make a good Adelphi melodrama, for we find a suffering heroine who is abducted by savages, a wicked uncle and his still wickeder solicitor, the hero, and his faithful savage attendant. All the bad people come to grief and all the good people are made happy, just as it should be but very rarely is. (3) *With Buller in Natal.* By G A. Henty. Pp. 384. Price 6s.—In this volume Mr. Henty has given us a most thrilling story, of which the relief of Ladysmith forms the theme. It will be read by young and old with much pleasure, for a brief account is given of every important action, from the battle of Glencoe to the series of operations that culminated in the rescue of Sir George White and his gallant force. The tale forms one of the most powerful stories from Mr. Henty's pen. The hero and his friends are British subjects resident in Johannesburg. When the war breaks out they escape to Natal and band themselves together under the title of "Maritzburg Scouts," and from first to last these "boy scouts" are constantly engaged in perilous and exciting enterprises, from which they always emerge triumphant. The book is well illustrated and is sure to give pleasure to boys all over the empire and cause them to anticipate the next war story already promised by the author.

MR. GEORGE ALLEN sends us *The Child's Picture Grammar.* By S. Rosamund Praeger. Price 3*s.* 6*d.* Grammar in general is a weary study, but Miss Praeger's delightful illustrations should make the way of learning a very primrose path. The illustrations are capital, especially those of the proper noun and of the preposition. The kitten in the latter is a gem of expression.

DIARIES.

MESSRS. RUDALL, CARTE, AND CO. again send us their admirable *Professional Pocket book or Daily and Hourly Engagement Diary.* The diary is divided into three parts containing four months each, and although primarily intended for the musical profession will be found no less useful for busy persons of other callings. The four-monthly parts have paper covers and the whole is enclosed in a neat leather case.

MESSRS. JOHN WRIGHT AND CO. of Bristol forward to us two issues of their *Visiting Lists.* One is marked A and the other B. Form A has fixed dates, while form B, called perpetual, has not, so that the list may be begun to be kept at any time of the year. The price of either is 5*s.* 6*d.* and they are strongly bound in morocco.

Analytical Records

FROM

THE LANCET LABORATORY.

TOBACCO (CRAVEN MIXTURE).

(J. J. CARERRAS, 7, WARDOUR-STREET, LONDON, W.)

THIS is a somewhat coarsely cut tobacco containing cavendish in association with pure bright Virginia leaf. The result is a blend which is quite cool-smoking in the pipe. On analysis the ash yielded normal results, there being no excess of chlorides which interfere with the convenient combustion of the leaf. We could trace no objectionable flavouring agents or added sticky substances which are so often present in order to give "substance," as it is called, to the leaf. The mixture is a blend of pure tobacco leaf, the proportion being such as to render it free from acridity and heat when smoked in a pipe.

(1) FORMIC SULPHUGATORS; AND (2) FORMITAS.

(THE SANITAS CO., LIMITED, BETHNAL GREEN, LONDON, E.)

The "Sulphugator" is designed to utilise the disinfectant properties of both sulphur dioxide and formaldehyde. In one form of the appliance a sulphur candle occupies a central space surrounded by a porous material containing formalin. As the sulphur candle burns the heat evolved drives formaldehyde from the porous jacket and thus both formaldehyde and sulphurous acid gas are evolved. In another form the "sulphugator" consists of three containers, the inner one being charged with formalin and surrounded by a sulphur candle. Outside the sulphur candle is a space for containing water or a solution of formaldehyde. Thus, steam, sulphurous acid gas, and formaldehyde vapour are simultaneously produced. These appliances seem admirably adapted for disinfectant and fumigating purposes. They should act also very effectually in destroying insect pests and other objectionable creeping things in stables, kennels, railway-trucks, &c. We have also examined a preparation known as "Formitas," a mixture of sanitas fluid and formaldehyde. It is a very pleasant combination of antiseptics in which the agreeable smell of sanitas predominates over the much less agreeable smell of formaldehyde. The mixture is doubtless an efficient disinfectant.

TIT-BITS BAKING-POWDER EXTRACT.

(A. BROWNING, 25, FINCHLEY-TERRACE, MURCHISON-ROAD, LEYTON.)

We found nothing novel in the composition of this so-called "extract." It contained the usual ingredients of an ordinary baking-powder, which interact when moistened with the production amongst other things of carbonic acid gas. A little starch is added to keep the powder dry. The materials employed are pure and we could find no objectionable reagents present, such as alum.

NARGOL.

(PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.)

Nargol would appear to be the newest chemical compound of silver and nucleinic acid. It is a fine, perfectly dry, brownish-white powder, easily soluble in water. It combines the bactericidal properties of an ordinary silver salt with at the same time the quality of not being rendered inert on coming into contact with albuminous substances. It is employed in genito-urinary diseases, it is stated, with decided advantage over silver nitrate, and is said to be free from irritating properties. It has also been used in ophthalmic, laryngological, and gynæcological practice. It may be regarded as a definite and soluble silver albuminoid.

New Inventions.

A SUBSTITUTE FOR BEER-BOTTLES.

WE have received from the Kannenbeer Company, Limited, of London, a specimen of a jug which they propose should be adopted instead of the ordinary bottle. It is made of stone ware and provided with a hinged lid fitted with an india-rubber washer. The lid when shut down is kept firmly closed by a metal clamp. The jug is glazed within and without and is obviously very easy to clean. The company claim that the exclusion of light will keep the beer in better condition than is possible in the ordinary bottle-glass bottle. The lid also being air-tight will, it is alleged, enable only a portion of a jugful to be used at one time, while the remainder can be sealed up and used later in good condition.

A BENEFICENT GIFT.—Lord Mount-Stephen has intimated to Lord Provost Fleming of Aberdeen that he is about to remit a cheque for £25,000 to discharge the debt on the Aberdeen Royal Infirmary. In 1846 his lordship was a patient of the infirmary.

COLD ASH CHILDREN'S HOSPITAL, SOUTH BERKSHIRE.—On Dec. 8th the foundation-stone of additional buildings, to be erected in connexion with this institution, was laid by Mrs. Palmer, wife of Mr. G. W. Palmer, M.P. for Reading. For some years the hospital has been successfully conducted under the direction of Miss Bowditch, at Cold Ash, where many crippled London children have been treated. Towards the outlay for the new works Mr. Palmer has contributed £200.

THE LANCET.

LONDON: SATURDAY, DECEMBER 15, 1900.

THE General Medical Council sat for eight days at its recent autumn session, three of which were mainly occupied with penal cases. Among the other important subjects which occupied the time of the Council were the new rules for obtaining diplomas in public health, the question in dispute between the Royal Colleges of Physicians of London and Surgeons of England and the General Medical Council, and the financial position of the Council. Besides these there were 30 or 40 other questions upon which the Council had to deliberate, so that even while we think that the Council occasionally spends too much time over its discussions, we admit that the discussions have to cover a great deal of ground. Sir CHRISTOPHER NIXON in the debate on the issues between the Royal Colleges of Physicians of London and Surgeons of England and the Council displayed a natural dissatisfaction with the powers of the Council. "The profession," he said, "look to this Council to secure uniformity of action among the medical authorities of the United Kingdom, and it should not be shown to them that after all the Council had only the power to express pious opinions." Sir CHRISTOPHER NIXON was well supported in his view by the majority of the Council who were resolved to adhere to their resolution on this subject. Members of the Council who spoke in this sense must have known that by adhering to a resolution which they have no means of enforcing, they were not advancing by one hair's breadth the adjustment of this unhappy difference. We ask the Council to be strong, but it must recognise that occasionally agreement to a compromise is the only way out of an *impasse*. It is a serious thing for the Council to demonstrate, not its power of securing uniformity, but its helplessness—which is what may be done by overstating its authority.

If the determination of the Council to adhere to its resolution means no more than to exclude from the Students Register of the Medical Council all who satisfy the two Colleges as to the efficiency of their education in the fundamental sciences, it is difficult to understand who is to get any satisfaction out of so barren a result. It is not pretended that registration on the Students Register can be enforced on students, or that it is necessary as a preliminary to medical education or to the acquisition of a medical qualification from any of the bodies. To compel applicants for registration on the Students Register, who have already satisfied the two Colleges, to encounter trouble and delay is only likely to irritate the students and the Colleges, to place the Council in an unenviable position, and to deprive the Students Register of a large number of students. The Council must, in our opinion, either go further and promote a large scheme for insuring uniformity of education or it will have to agree to some *modus vivendi*. We do not admire the unbending attitude of the Colleges, or the tone and style in which the case between them and the Council is stated. Their own representatives in the Council voted against the proposal to try to find an amicable settlement of the points in dispute, though this was the very suggestion of their legal adviser. It is easy to see that the recognition of schools as medical schools may be open to abuses. But, on the other hand, the Royal Colleges of Physicians of London and Surgeons of England appear to have taken much trouble to ascertain the equipment of the schools which they have recognised, and to have reason to believe that many of them are more efficiently provided with the means of teaching chemistry, biology, and physics than are some of the medical schools. The General Medical Council has not the means or the time to satisfy itself on this subject It is difficult to understand how it can proceed to approve or to disapprove of institutions which it has no means of inspecting properly. Though counsel on both sides may agree, it is still doubtful if the Council can compel the licensing bodies to comply with the requirements and recommendations contained in its resolutions with reference to the course of preliminary study to be gone through by students. Under these circumstances we can only impress on both parties the obligation to give and to take a little. Both sides should attempt, and attempt quickly, to find some means of upholding the influence of the General Medical Council without detracting from the individual responsibility of separate medical authorities.

We cannot help feeling that the General Medical Council in its individual capacities loses sight somewhat of its responsibility as a whole, which is towards the public and the medical profession, and not towards a group of universities and corporations. We think our feeling must be shared by Dr. PYE-SMITH. Dr. PYE-SMITH, who is always listened to with much respect in the General Medical Council, expressed the opinion at the late meeting that the Council would never do its best until it was reduced in size to one-half of its present number and until the reporters were excluded. The first part of Dr. PYE-SMITH'S forecast is flattering to us, for we have always held that the Council is too large; the second part is not flattering to his colleagues in whichever way it is regarded. There is, however, no chance of the Council being diminished in numbers at present, for as the direct representatives require to be increased, and not diminished, in numbers the only way that diminution could be effected would be by depriving certain universities and corporations of a separate voice. In some directions this might be a reform, but there is no tendency towards it. In spite of the conjunction of the Royal Colleges in the three divisions of the Kingdom each body likes to assert distinctness and individuality at the General Medical Council. There is unhappily no sign of conjunction of universities in any division of the kingdom even for examination purposes. Each body requires its separate mouthpiece and Parliament is not likely to alter the privileges that are now enjoyed by any of them. And we should oppose the exclusion of the reporters as a backward step There may be members of the Council who speak for the sake of being reported, but the utility of the Council should not be made to suffer for the vanity of a few. The Council is a public body. It has the enormous power of erasure from the Register and it is of the utmost importance that proceedings attending such erasure should take place openly, for the instruction of the public on the one hand and to give fair play to the accused on the other. The Council has great duties in relation to education and must express opinions on measures of legislation having medical bearings, in regard to all of which publicity of statement may be of the greatest importance. The members of the medical profession are entitled to know the views and the proceedings of a Council which they support with their fees and which orders their education and conduct. The public have at least an equal right to know what measures are being taken to keep medical education up to a proper standard and to supply an accurate register of qualified medical men.

THE epidemic of peripheral neuritis which was traced to the consumption of beer containing arsenic is, we hope, in process of being arrested. Its causes, so far as they may depend on the use in brewing of glucose or "invert" sugar prepared with impure sulphuric acid, have been traced, and in all parts of the kingdom medical men are on the alert to detect and deal with new foci, while the publicity given by the press to the matter as one of widespread interest and obvious emergency has helped to avert the danger. Fresh cases have, however, been announced since our last issue, whilst several inquiries held by coroners have brought into prominence a question which may come before any of our readers in the near future—Who, if anyone, is liable to compensate those who have lost relatives by death? This is a most important point where those affected are from the nature of the case largely drawn from the wage-earning class. It will be well that medical men should make themselves to some extent familiar with the law in relation to the occurrences.

Some persons have apparently lost their lives through drinking beer containing arsenic, and it need hardly be said that where a person's death is caused by the wrongful act, neglect, or default of another, and the injured person, if he had lived, could have maintained an action, Lord CAMPBELL'S Act enables relatives within certain limitations to recover compensation for their loss. The recent epidemic seems likely, therefore, to produce a large number of such claims; but the alleged facts upon which they will be founded are without any close parallel, and if the liability is seriously disputed by those whom it is sought to make responsible, some time may elapse before it is fully established. Yet, if we may hazard an opinion on so debateable a topic, it seems reasonable to suppose that someone will be found liable to pay compensation in some cases, while those seeking it will direct their efforts against the brewers with the best chance of success. Possibly some difference may arise between publicans selling in "tied houses" and those who do not, but we may assume that the public-houses for the most part will be found to have been "tied," a circumstance which needs no definition, but which results in the publican being virtually the agent of the brewer, or in any case in his selling a beer the source of which is well known to the consumer.

The brewers have hitherto met the emergency with every effort to abate the evil, and it is probable that they will also show a conciliatory spirit if threatened with litigation, but the door to unfair or mistaken claims is a very large one, so that the brewers must not be blamed if they take every step to protect themselves and to sift the statements of those who may proceed against them. It will be seen at once that the purely medical evidence may be of enormous value to persons making a claim upon the brewers, while the evidence of medical officers of health, public analysts, and borough chemists may be of equal importance. The claimants will, presumably, have to show that the person affected died from, or exhibited symptoms clearly indicating, arsenical poisoning; that such person drank beer from a certain public-house; and that samples of beer from that public house contained arsenic in quantities sufficient to account for the symptoms complained of. It will hardly be necessary to go through his dietary to show that he *did not get the arsenic in any other way*; that will be a matter for the defendants to prove if they allege it. The kind of scientific evidence that plaintiffs will require is shown by the communications that have appeared in our columns, and every medical man who finds himself confronted with what he believes to be a case of arsenical poisoning from beer-drinking must be prepared to give in a court of law similar information concerning his patient.

The report by Professor SHERIDAN DELÉPINE and Mr. C. H. TATTERSALL[1] says: "Every case we have followed up (about 100) can be traced to beer in the brewing of which glucose or sugar from one manufactory was used." If the arsenic can be traced as far back as the brewer it will scarcely be necessary to follow it further, although the brewer may ultimately have a remedy against the person who supplied him with glucose, while the manufacturer of glucose may in his turn some day maintain a claim against the person from whom he bought his sulphuric acid. Much will presumably turn in all such cases on the amount of knowledge on the part of the vendor of the purposes for which the thing sold was to be used. If anyone is sued for damages in consequence of the epidemic which we are now considering, whether he be publican, brewer, manufacturer of glucose, or manufacturer of sulphuric acid, he will be sued on one of two grounds—either because he sold something with a warranty, express or implied, that it was fit for its purpose (in which case should it prove unfit he would be liable whether negligent or not), or because having a duty towards his purchaser he neglected that duty. Let us take first the case of the publican. It appears from decided cases, the principal ones[2] arising out of the sale of diseased meat, that there would be no implied warranty at common law by him that the beer was wholesome, and the 14th section of the Sale of Goods Act, sub-section 1, does not seem to affect the ordinary sale of beer to a customer in a public-house. It apparently imports a warranty only where the buyer relies on the skill and judgment of the seller—a relation which does not seem to exist where a customer calls for a pot of beer in a public-house. Nor can a publican be reasonably held to be negligent because he does not know that the beer which he retails, but does not make, contains a minute but injurious quantity of arsenic. There can hardly be a duty incumbent upon him to make the inquiry or to have the knowledge necessary for such a discovery. With regard, however, to the brewer the case is different. Like the publican, he knows that the beer is going to be drunk by human beings Like the publican, he may not be held to warrant it wholesome, which would make him civilly liable if some murderous assistant were to poison it wholesale. But it is at least arguable that he should know the chemistry of his trade and that the chemist whom he employs should have his mind directed to all possible, as well as obvious, dangers. The use of glucose and "invert" sugar is of comparatively modern date. The employment of these substitutes has provoked much comment and remonstrance. The brewers who have introduced these ingredients into beer have done so for their own convenience, and it may well be urged against them that it was their duty to see that the chemically obtained sugars which they bought were pure. The danger of arsenical poisoning may not have been pointed out to them in terms by their critics, but it was they themselves who maintained that the new system of brewing was wholesome, and it was their business to see that it was so.

[2] Emmerton *v.* Mathews, 7, Hurlstone and Norman's Reports, 586; Ward *v.* Hobbs, 4, Appeal Cases, 13.

◆

IT was recently decided by the board of management of the National Hospital for the Paralysed and Epileptic, acting upon the advice of the Lord Chancellor, one of their body, that an inquiry into the management of the hospital should be held by the Right Hon. Sir FORD NORTH, a retired judge of the High Court We announced this last week.[1] Sir FORD NORTH's inquiry was to be directed towards obtaining information for a report upon the allegations made by the medical staff concerning (to quote the terms of reference): "(*a*) the diet of the patients; (*b*) the condition, care, and treatment of the patients; and (*c*) the nursing of the hospital—brought forward, under the headings above quoted in the statement, dated May, 1900, issued by the medical staff to the governors on or about June 16th, 1900." As soon as the terms of reference of Sir FORD NORTH's proposed inquiry were made known, the medical staff of the hospital decided that they could not recognise the court. Sir FORD NORTH, they pointed out, had been invited to make his investigations solely by one of the parties to the controversy—namely, the board of management; and, secondly, the scope of the inquiry was limited to the domestic conditions of the hospital and appeared to exclude from consideration the all-important topic of the constitution of its management. The attitude thus taken up by the medical staff was absolutely consistent with the position that they have occupied throughout They have asked for inquiry, but for inquiry into all the matters at issue between themselves and the board of management. An investigation of certain charges which they considered it their duty to make many months ago will form part of such an inquiry, and not the least important part. But when the board proposed, instead of a thorough investigation of the whole situation between the two parties, a limited inquiry, to be conducted by a court of their own appointment into one side issue, the medical staff very properly refused to have anything to do with the matter. We now learn that Sir FORD NORTH'S proposed inquiry has been adjourned *sine die*, and we may be permitted to wonder what the board of management ever expected to take by such an inquiry We have every desire to credit both sides of this unfortunate controversy with good faith, therefore we must suppose that the request to Sir FORD NORTH to obtain information for a report upon the accuracy of the statements placed before the governors of the hospital last May by the medical staff was made with the belief that such a partial inquiry would meet the case But while we credit the board of management with an honest attempt at reform we cannot compliment them upon their sagacity. They had before them the clear and reiterated statement of the medical staff that they would have nothing to do with a partial inquiry, so that the refusal of the medical staff to recognise Sir FORD NORTH'S court was only to be expected. And if in spite of this refusal the inquiry had been held, in what way would the report have been conclusive? Quite apart from the fact that the most important witnesses would have been absent, Sir FORD NORTH, a learned lawyer, is not an expert on hospital feeding, on nursing, or on sanitation; he was provided with no medical assessor; and he was invited to discharge his unenviable duty by one party—the accused party—to a controversy No practical purpose whatever could have been served by such an inquiry. To put it bluntly, if the report of Sir FORD NORTH had been a favourable one it would have been regarded as a whitewash. The only satisfactory mode of settlement is the appointment of a perfectly independent committee with a free hand to inquire into all the points at issue between the medical staff and the board of management, together with the admission of representatives of the staff to the board.

Annotations.

"Ne quid nimis."

THE SANITATION OF BARGES.

THE last issued half-yearly report of the medical officer of health of the Port of London, a valuable if somewhat belated document, deals in some detail with the sanitary conditions which obtain on the "dumb craft" which do so much of the carrying trade in the lower Thames. These craft are said not to be inhabited because the men who navigate them do not, or at any rate are not supposed to, sleep on board. The owners of the vessels plead that it is unreasonable to expect that they should be fitted up with sleeping accommodation, because they do not wish the men to sleep during a voyage, and if the crew remain on board when the vessel is moored it is for the purpose of keeping watch over the cargo, and therefore facilities for sleep are distinctly contra-indicated The owners state also that as the men who work these craft are constantly being changed it would be practically impossible for them to exercise due supervision over a sleeping cabin and that they would therefore be constantly put to great expense in the cleansing and repair of the place There is perhaps less in this contention than in the former one, although Dr. W. Collingridge, the writer of the report, who is intimately acquainted with the practical working of all river craft, considers that it is not unreasonable that the barge owners should altogether object to provide sleeping accommodation on board. He insists, however, that "a clean, weather-tight, well-ventilated cabin, provided with a stove suitable for warming and cooking purposes," ought to be provided in all cases. With this recommendation we cordially agree. It is part of the duty of the Port Sanitary Authority to keep all river craft under constant supervision, and when it is found that one is in so insanitary a condition that it can be classed as a nuisance an order under the Public Health Act is served and measures are usually taken at once by the owner to abate the nuisance. This method of proceeding, however, is found not to be adequate, for there are many cases in which cabins are undoubtedly unfit for their purpose and yet fail perhaps to reach the point of being "nuisances" within the meaning of the Act. As everyone who has sailed much on the lower Thames is fully aware, a large number of barges are used for carrying offensive cargoes, such as manure and house and manufacturing refuse, and the river is undoubtedly the best channel by which the refuse of London can be removed, and as the prolonged retention of such offensive matter would be injurious to the community the more rapidly it can be got rid of the better it is. It follows that no unnecessary restrictions should be put upon this trade, but it is necessary that the process of removal should be done as far as possible in such a way as to be injurious neither to the general public nor to those engaged in the work. It is well that the efficient by-laws which have been made for the protection of the public are generally obeyed. During the half-year under review, however, the owners of 11 barges were summoned for neglect in carrying out the by-laws and in each case a fine was imposed. The by-laws at present in force have, unfortunately, no reference to the health of the inhabitants of the barges. The craft which carry refuse are constructed without any attempt being made to prevent the foul gases which arise from the cargo from passing into the cabin, and, as a rule, old barges are used for the trade. Dr. Collingridge points out that to ensure the purity of the air in the cabin it is necessary that the barges should be constructed with a double bulkhead, that there should be a space between the bulkheads, that this space should be freely open to the air, and that a pump should be provided to free it from foul fluids. These precautions, he urges, are inexpensive and easily practicable. They should be made compulsory. We entirely agree with this recommendation, which would do no more than enforce a necessary sanitary provision which is already enforced in the case of all canal boats.[2] There can be no reasonable doubt that the unhygienic conditions which exist on barges have a deleterious effect on the crews. The Thames bargee is not generally considered to be a delicate person, nor is his appearance usually that of an invalid—it might, indeed, be difficult to convince an intelligent English jury that men of the physique of the bargee are living under insanitary conditions. As a fact, however, the state of the barges has been so noxious in some cases that death has undoubtedly resulted from a neglect of the structural conditions which have been indicated as necessary in the case of vessels carrying foul cargoes. Dr. Collingridge quotes two cases which are absolutely convincing on this point These cases are briefly as follows: On Jan. 30th, 1900, a ketch was found off Silvertown. On examining the cabin the inspector found the master and his wife both dead They had been suffocated by the fumes of the cargo. which was "saccharine scum," a substance which gives off large quantities of carbonic acid gas, the inhalation of which was proved by the medical evidence to have caused the deaths. The second case occurred on July 30th, 1900, when two men were found dead in the cabin of a sailing barge. The cargo consisted of market and dustbin refuse in a state of decomposition. At the inquest the medical evidence proved that death was caused by asphyxia due to gases given off from the cargo. An examination of the barge showed that there was a free passage through which the foul air could pass from the hold to the cabin. In this case the jury recommended that "barges conveying manure and other impure cargoes should be specially constructed." Dr. Collingridge advises that a by-law should be framed similar to the regulations in force in the case of canal boats. We entirely agree with the importance of this recommendation and see no reason for delay. We therefore earnestly commend the matter to the consideration of the Port of London Sanitary Committee and to the President of the Local Government Board

ARSENIC IN WHISKY?

IT was certain that there would be a tendency to exaggerate the possibilities of evil arising from the recent revelation of arsenic being found in the sugar used for brewing beer. After all, it is but natural to wonder whether arsenic might possibly gain entrance into preparations other than beer, which either contain glucose or are a product of its fermentation. Thus sweetmeats, golden syrup, honey, jam, and, lastly, whisky have fallen under suspicion. It is gratifying to know that so far, although a great number of analyses have recently been made, arsenic, at any rate in London, has not been found in the first four. It is fairly certain that artificially derived sugar is employed in the production of spirits and the question remains to be answered whether if there were arsenic in the sugar it would pass into the spirit on distillation. All spirits, of course, are distilled. We have this week conducted a simple experiment which shows that arsenious acid does not pass over with spirit in the still. Indeed, if a spirit contained arsenic in the form of arsenious acid the latter could be easily separated in this way. We placed a few ounces of whisky in a small still with about 20 grains of white arsenic or arsenious acid and then proceeded to distil the mixture. In spite of the very large poisonous quantity of arsenic in the still not a trace of arsenic passed over or could be detected in the rectified spirit. The whole of the arsenic was left behind. According to this experiment, therefore, no fear need be entertained of arsenic occurring in whisky, though the poison may be present in the sugar substitute employed. This experiment was undertaken because it had been reported that some of the cases at Manchester and Shoreditch occurred in regard to patients who had not been beer-drinkers but whisky-drinkers. We have neither received nor heard of any confirmation of these cases. In regard to the epidemic of arsenical poisoning by means of beer we are glad to note that the Local Government Board is addressing a circular letter to local authorities recommending them to cause samples to be analysed both of beer and of other articles of food in which glucose and similar substances are used. Last week in an annotation upon the subject we wrote: "We venture to suggest that a special Government order should be issued instructing all county authorities to institute an analytical inquiry in their districts." We are glad that the action herein intimated is to be definitely taken.

ALLEGED "CONSUMPTION CURES."

SOME prominence has recently been given in the lay press to another alleged cure for consumption. We regret that the correspondence was taken part in by a medical practitioner who wrote that he had used the "remedy" in a large number of cases with great success. Such a statement in a daily newspaper cannot be too strongly deprecated, as it amounts to advertisement pure and simple. If any form of treatment for any disease has given satisfactory results it is only just that such therapeutic measures should be made known, either through one of the medical societies or in the columns of the medical press, but when published in the daily press it can only tend to bring discredit both upon the treatment itself and upon the practitioner who seeks such channels to make his name known. The drug, which is claimed in this instance as a "new remedy," is arsenic or one of its derivatives. Two names are associated with the drug through no fault of their owners—namely, Professor Armand Gautier and Dr. Hoff of Vienna. Arsenic has been used in the treatment of pulmonary tuberculosis in this country for a number of years, consequently there is nothing "new" in its employment Different authorities use varying doses, and it is well known that tolerance of the drug is generally speedily established—witness its use in chorea and children can without inconvenience take 15 minims of Fowler's solution three times a day if the dose is slowly increased and the patient is carefully watched. One preparation of arsenic is comparatively new—namely, cacodylic acid, and it is claimed that the drug can be pushed to its full action more conveniently by this means than by employing the preparations in ordinary use. Cacodylic acid is arsenic acid in which two hydroxyl groups are replaced by two molecules of the methyl group. Our object, however, is to protest against its use being exploited in the lay press, although, as already stated, the two authorities whom we have mentioned are not in any way to blame for the prominence which has been given to their names. Frequent references have been made to the drug in previous issues and a list of references will be found in another column.

[2] Regulations of the Local Government Board under Canal Boats Act, 1877 (47 & 48 Vict c 75), March 20th, 1878.

A RECENT DEVELOPMENT IN ADVERTISING.

So far as its own members are concerned the medical profession in this country remains true to its ideals and abhors the practice or permission of advertisement It needs no deep thought to discern the degradation into which a learned profession must inevitably sink if once success in its ranks comes to depend less upon the merits than upon the advertising powers, the immodesty, and the assurance of its members. Yet while medical men thus refuse to be active participators in advertisement there is no class, we suppose, more persistently victimised by advertisers of all kinds. What practitioner's waste-paper basket is spared for a day even from elaborate circulars describing the particular merits of some outrageously-named drug or from presentation copies of periodicals whose pages present articles that are but the thinly disguised advertisement of a patent medicine or a proprietary hygiene establishment? We mention the waste-paper basket, but no man's basket alone can cope with the advertisements that reach him through the post. He must have, in addition, some repository for the more substantial waste that is showered upon him. Bottles of mineral waters from all corners of Europe and America, little boxes of substances that represent the latest enterprise in making medicines palatable, ointments, lotions, biscuits, and extracts, all alike reach the medical man who neither requests nor desires this bewildering accumulation. It may be urged that beyond some domestic inconvenience this prolific advertisement does the medical man no harm and occasionally perhaps even leads him to notice a useful preparation that he might otherwise have missed. Unfortunately, however, advertisement even without encouragement will not stop short at the comparatively harmless methods we have alluded to. The success of advertisement from the commercial point of view is undoubted. Consequently, advertisers are ever on the alert for some new means by which to catch the eye or to arrest the attention of probable customers until, without ever actually transgressing the laws of bribery and corruption, methods are practised that cannot fail to damage the self-respect of any who may allow themselves to be practised upon. We have no fear that such a bait as the "Craigside Hydro, Llandudno," holds out to the medical profession will be readily swallowed, but as an example of an evil and perhaps new method of "pushing a concern" we are glad of the opportunity of alluding to these matters that a correspondent puts in our way. This gentleman, as well as no doubt many others, received together with a brochure relating to the Craigside Hydropathic Establishment a coupon the presentation of which will be accepted in payment of account for three days' stay at the "hydro." Such benevolence on the part of the institution has only one significance It says in effect, "We will pay you for a three days' holiday here, afterwards send your patients who will pay us" We know nothing of the establishment in question; it may be, and very likely is, in every other way admirable, but of this we are quite certain, that such a means of advertisement as we have described, so far from recommending its object to medical men, will only arouse their suspicions and delay them from seeking its benefits either for themselves or for their patients.

ATROPHY OF THE MUSCLES OF THE SHOULDER AS AN EARLY SIGN OF PHTHISIS.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Oct 26th M Emile Boix called attention to an early sign of phthisis which has not received much attention—atrophy of the scapulo-thoracic muscles on the affected side. In advanced cases, of course, such atrophy is well recognised. M. Boix relies on inspection and palpation rather than on measurement to detect slight differences between the two sides. Inspection of the shoulders both from the front and the back must be carefully carried out in a good light. If necessary it may also be performed with the patient lying down, both on his abdomen and on his back; or better still, the patient may be seated. Palpation will corroborate the evidence derived from inspection. With the tips of the fingers the thickness, consistency, and elasticity of the muscles are appreciated and at the same time the habitual tenderness—a sign of the first importance—is discovered. The difference between the two sides can also be appreciated by pinching between the fingers the fleshy mass above the clavicle and spine of the scapula M. Boix finds that in phthisis muscular atrophy is more marked on the side in which the lesions are more advanced and is unilateral if the lesions are unilateral Even when the subject is very emaciated a difference between the two sides will be found in the volume and consistency of the supra-spinatus, trapezius, and pectoral muscles, and sometimes of the deltoids. Muscular atrophy is an early sign, but is not a primary sign, of phthisis Its value consists in that it draws attention to the affected apex and confirms the diagnosis at a time when only modified respiratory sounds without adventitious sounds are present and the disease can only be suspected The atrophy in advanced cases affects more or less generally the muscles of the shoulder; in the beginning, on the contrary, it is partial. Sometimes the supra-clavicular hollow is more pronounced on the affected side, sometimes the sub-clavicular plane is retracted, and sometimes the supra-spinous mass is less full than on the other side. A source of fallacy is that the muscles of the left shoulder are generally less developed than are those of the right; but a perceptible difference, especially in the form of the "partial" atrophy described above, constitutes a presumption in favour of phthisis The fact that the right side is generally first affected or most affected in phthisis increases the value of the symptom of muscular atrophy. As to the

Scotland" which should have the attention of all intelligent and religious people. In the year 1899 176,000 persons were apprehended or cited for these offences; and the numbers constitute a record. The following are the five towns which have the worst record: South Queensferry has 1424 cases of drunkenness and disorder per 10,000 population; Falkirk, 1066 cases; Linlithgow, 830; Cumnock, 770; and Clydebank, 756. We venture to suggest that the medical profession of Scotland, apart from all extreme theories and practices, should take this subject into its consideration with a view to some public statement of the medical and pathological bearing of such statistics.

A NEW MUZZLING ORDER.

AN order of the Board of Agriculture in the *London Gazette* of Dec. 8th provides that every dog brought to Great Britain from any other country except the Channel Islands and the Isle of Man shall, unless accompanied by a properly issued licence authorising its landing, be chained and muzzled in some inclosed portion of the ship, while the latter is lying at any port in Great Britain. In case of default the owner of the dog, the person for the time being in charge thereof, and the master of the vessel may be proceeded against under the Diseases of Animals Act, 1894.

INDIAN AND COLONIAL ADDENDUM TO THE BRITISH PHARMACOPŒIA, 1898.

BY the courtesy of the General Medical Council we have received for review an early copy of the above. The copy is avowedly imperfect and subject to slight verbal and typographical alterations, and it cannot yet be obtained from the publishers, since the price has not been determined by the Treasury. We understand that it is impossible to give any idea of the precise date of publication, but that meanwhile copies similar to that supplied to us may be consulted at the offices of the General Medical Council, in London, Edinburgh, and Dublin.

THE REGENT'S CANAL AND THE PUBLIC WEAL.

THE Regent's Canal was intended to be, and originally was, an attractive water-way. The general design of the canal and the details of the work alike show that it was arranged with a view to be beautiful as well as useful. Its primary object was, of course, to transport heavy goods. The work was projected in the early part of the present century at a time when food was scarce, and it was said that such a canal would diminish the cost of carting and lessen the number of draught-horses, "whereby," urged the promoters, "much land now applied in the growth of provender for them may be more beneficially used in the culture of food for mankind." The project took statutory form in the year 1812 (52 Geo. III., c. 195), and the work, begun on Oct. 14th of that year, was completed and opened for traffic in 1820. The company obtained from the Consolidated Fund the use of a sum of £200,000, and later another sum of £100,000 was advanced on the security of the undertaking (1 & 2 Geo. IV., c. 43). From these facts it will be seen that the Regent's Canal was projected nominally in the public interest and that to assist in carrying out the work the use of the public credit was granted. It follows from this that the business ought to be carried on in a way to serve, and not to interfere with, the public weal. It cannot be said that these conditions have been, or are, fulfilled. For many years past the accessories which made the canal banks attractive and beautiful have been neglected, the towing-path has fallen into a state of bad repair, and, worse than all, the water in the canal, instead of being clear and bright, has been allowed to become filthy and putrid. Every summer lately during the warm weather the stench from the canal has been most offensive. A report recently presented to the Public Health Committee of the London County Council has called attention to the foulness of the water, and some rather curious suggestions were made as to what ought to be done in the matter. One councillor gave it as his opinion that the canal should be done away with—a proposition which would, of course, require an Act of Parliament to give it statutory force. Another councillor thought that the Thames Conservancy should have power to prevent the canal water from passing into the Thames. This proposal also could only be carried out under a special Act passed for the purpose, and if then it could be enforced it would necessarily render the state of the canal more foul than it is at present. The report of the Health Committee of the London County Council is, however, more worthy of consideration. The Regent's Canal Company, it is said, are authorised to sell water from the higher levels outside the county and they exercise this right, the proceeds of the sale forming part of their revenue. For the purposes of navigation the water, instead of being allowed to flow down from the higher levels, is pumped back from the lower levels. The committee point out that the good effects of flushing the canal with water from the upper levels has been practically proved. Some years ago several of the vestries complained of the foulness of the canal and the company allowed nearly 16,000,000 gallons of water to pass down, whereupon the nuisance was quickly abated. In December, 1893, the Health Committee conferred with representatives of the sanitary authorities through whose districts the canal passed, and in February, 1894, the London County Council took counsel's opinion as to whether the Attorney-General could, if called upon by the Council, proceed by public indictment against the canal company for creating a public nuisance by neglect in the management of their business. The Council were advised that the case was not one in which the Attorney-General would be likely to take proceedings until every effort had been made to stop the nuisance under the Public Health London Act (1891). It does not appear from the report that the Council have made every, or indeed any, effort to avail themselves of the Act of 1891, nor is any explanation given as to why they have neglected to use so ready and effective a weapon, which appears to be the more curious inasmuch as the counsel who advised them pointed out that in his opinion the Council were not empowered to pay the expenses of an action by indictment. The Public Health London Act (1891) was passed for the very purpose of giving the local authorities power in all matters relating to nuisances. It is an excellent Act and if use were made of its provisions London would be a very much cleaner, a much more beautiful, and a much more healthy place than it is at present. We have every confidence that the new metropolitan boroughs will effectively carry out the great duties committed to their care and will abolish nuisances which have eluded both the apathy of the vestries and, if it may be so called, the vigilance of the London County Council.

PLUMBING AND THE NEW CORPORATIONS.

THE annual Livery dinner of the Worshipful Company of Plumbers, held on Nov. 27th at the Fishmongers' Hall was a gathering of more than usual interest. It afforded the Lord Mayor of London, and many of the mayors of the oldest municipalities in the country, the opportunity of meeting their more recently created brethren of the municipal world, including the 28 mayors so recently enrolled in Greater London. In fact, as one of the speakers (Mr. Robert Crawford of Glasgow) said: "The Plumbers' Company had succeeded in creating, in a way impossible for any other body, a federation of all the municipal and county authorities of the United Kingdom and of those interested in the sanitary question from almost every standpoint." The speakers generally insisted on the importance and necessity of legislation in some form in order to give to the public a measure of protection from the evil effects of ignorance or malpractice on the part of those undertaking plumbing work. A meeting was held at the Guildhall, London, during the week between representatives of district councils and the Worshipful Company of Plumbers, in furtherance of some form of legislation.

CHRISTMAS SHOPPING AND PUBLIC HEALTH.

WITH the approach of Christmas an increased stress of work presses heavily on shopkeepers and their assistants. In these days of intensified competition it is not surprising that shops are kept open late at night, but such overwork is not healthy and anything that can help to give all classes sufficient leisure to recoup from the exhaustion of their daily avocations is of public benefit. In America some ladies have taken a generous initiative in this respect and have formed what they term the Consumers' League. The members of this organisation point out the inconsistency of subscribing to hospitals while at the same time the subscriber will go late to a store and "badger a saleswoman into a fit of nervous prostration." Consequently the members of this league are expected to refrain from making any purchases after 5 o'clock in the afternoon and not to allow parcels to be sent to their homes later than 6 o'clock. Nothing can be more simple than this suggestion. If it could be carried out there would be an end to the shop assistant's grievances, and this without any sort of legislation or police interference or the expense of maintaining an army of inspectors to see that the law is enforced. Unfortunately a league of this sort is only likely to be supported by a thoughtful and unselfish minority of altruistic humanitarians. There is also a material obstacle in the fact that many persons are at work till after 5 o'clock and therefore have not time to do any shopping before that hour. Nevertheless, only good can result from calling attention to this question, and this is, more than any other time of the year, the season for doing so. If only those who have the leisure to do their shopping before 5 o'clock made it a firm rule never to purchase anything after that hour this alone would suffice very materially to relieve the strain on tradesmen and their assistants. Then a great deal might be done by taking time by the forelock instead of leaving purchases, especially Christmas purchases, to the very last moment. In a word, and in defence of the health and happiness of a large section of the community, we appeal to all intending purchasers to think not only of themselves and their purchases but also of the interests of those tradesmen with whom they intend to deal. It will not cost more to buy earlier in the day and somewhat sooner in the season, but it will distribute more evenly the work that has to be done in satisfying the demands of the consumer and thus will mitigate the unhappy and unhealthy strain that weighs so heavily on shop assistants at Christmas time.

WOMEN HEALTH OFFICERS.

THE Vestry of St George-the-Martyr, Southwark, shortly before its existence terminated published the fact that out of a total of 1331 deaths which occurred during a certain period, 765, or nearly 60 per cent., had been among children under five years of age. To those intimately associated with the study of disease amongst the inhabitants of the poorer parts of London this will occasion no surprise. The out-patient rooms in the children's department at our general hospitals and in the special hospitals devoted to the treatment of the diseases of children are crowded with the results of maternal ignorance and neglect. The want of knowledge displayed by the mothers as regards the diet of infants and young children is astounding and can only be fully appreciated by those who are brought frequently and intimately into contact with the results of defective feeding. The general want of hygiene in the dwellings of the uneducated classes is also astonishing and greatly adds to the general death-rate. In several of the large provincial towns, including Birmingham and Sheffield, officers have been appointed to attempt to instruct the women as to the way in which their children should be fed and their rooms kept clean. The Limehouse Vestry applied for permission to appoint a similar officer last year, but were refused. The Vestry of St. George-the-Martyr, Southwark, which published the figures already referred to, appointed a lady under the somewhat cumbrous but significant title of "Lady Sanitary Officer and Health Inspector." She will be expected to visit the homes of the poor and to instruct them how to get rid of bad smells and vermin, to point out to the mothers the prejudicial effect of insanitary conditions of health, especially as regards children, and where sickness exists to advise as to the nursing of the patient, the preparation of the food, and the administration of remedies, also to advise as to the management of the house where a patient suffering from pulmonary tuberculosis is resident, both in the interests of the patient and of the others living in the house. She is also to instruct the women in various domestic details, such as the cleaning of the rooms, passages, and yards, and in the cooking and preparation of the family meals. In theory the idea of such an officer is excellent, and the late Vestry of St. George-the-Martyr, Southwark, deserves the warmest praise for appointing one. No doubt a large amount of good will result. The lady in question will require an immense amount of tact and perseverance, and we wish her every success, but whether she will succeed in the Herculean task of cleansing the Augean stables of slum ignorance and prejudice remains to be seen. The effort, however, is certainly worthy of a trial, and it is to be hoped that the newly-formed municipal bodies will imitate the example of Southwark and appoint similar officers throughout London.

NEALE TESTIMONIAL FUND.

WE are requested to state that the Committee have decided that the testimonial to the late Dr. R. Neale shall consist of (1) a life-size portrait in oils by Mr. T. B. Kennington, the painter of the excellent memorial portrait of the late Professor Hopkinson; and (2) four silver bowls, suitably inscribed, to be presented to the four members of Dr. Neale's family. As soon as possible a list of subscribers and a balance sheet will be published.

AT a meeting of the council of the Hospital Sunday Fund, held under the presidency of the Lord Mayor, at the Mansion House, on Dec. 7th, on the motion of Dr. J. G. Glover, seconded by Sir Henry Burdett, the following motion was unanimously adopted: "That in regard to the grant to the National Hospital for the Paralysed and Epileptic, Queen-square, W.C., the basis of which has been already arranged by the distribution committee for the current year, the distribution committee be empowered to pay, out of funds in hand, the award, on being satisfied of the settlement of the existing differences before May 1st next."

LORD ROBERTS will honour the Irish Medical Schools' and Graduates' Association by his presence at a banquet to be given by the members to their distinguished fellow-countryman on his return from South Africa Lady Roberts and her daughters have also accepted an invitation to be present on this occasion.

THE death is announced of Mr. R. G. Glenn, the Recorder of Croydon. He was born in 1844 and was a "Grecian" of Christ's Hospital. His name should be widely known to medical men, for he was the author of "A Manual of the Laws affecting Medical Men" and of the Legal Abstract published in Churchill's "Medical Directory."

DR D. E. ANDERSON of Paris, a graduate of the London and Paris Universities and former physician's and obstetric assistant at University College Hospital, has been elected to the post of visiting physician to the Hertford British Hospital, Paris.

AT a general monthly meeting of the Members of the Royal Institution held on Dec. 3rd Dr. Allan Macfadyen was announced to have been appointed Fullerian Professor of Physiology for three years, the appointment dating from Jan. 14th, 1901.

IT is announced that the Queen has granted to the Royal Society, for the purposes of a national physical science laboratory, Bushey House, Bushey Park, formerly the residence of the Duc de Nemours.

DURING the week ending Dec. 6th 46 fresh cases of plague were registered at Mauritius, 26 of which were fatal. The total deaths from plague during the week numbered 33.

THE *London Gazette* of Dec. 11th contains new rules made by the Home Secretary for retreats licensed under the Inebriates Act.

MR. W. H. BATTLE, F.R.C.S. Eng., has been elected surgeon to St. Thomas's Hospital in the room of the late Mr. W. Anderson.

REPORT TO THE

HOSPITALS SUB-COMMITTEE OF THE MANCHESTER SANITARY COMMITTEE ON THE OUTBREAK OF ARSENICAL POISONING NOW IN PROGRESS IN MANCHESTER.

DR. JAMES NIVEN, Medical Officer of Health of Manchester, has presented the following report to the Hospitals Sub-committee of the city on the outbreak of arsenical poisoning in Manchester:—

The medical officer of health begs to present to this sub-committee a report on the outbreak of arsenical poisoning now running its course. On Nov. 20th Dr. Reynolds called at the Health Office and informed the medical officer of health that he had obtained well-marked reactions of arsenic in a sample of beer which he had examined. For some months there had been a large number of patients coming into the Union Infirmary with well-marked and fairly uniform symptoms, and there were at present a very large number of these cases in the wards. They were all beer-drinkers and drank the cheaper kinds of beer and stout. For some time he had suspected the presence of some deleterious agent in the beer and latterly the symptoms had suggested arsenic. He had therefore procured a sample of a beer which was pointed to by many of the cases, tested it, and found arsenic. He also informed your medical officer of health that another sample of beer submitted to Professor Dixon Mann had been found to contain arsenic, thus confirming his observation. Previous to Dr. Reynolds's intimation on Nov. 20th your medical officer of health was aware of nothing indicating either an outbreak of a fresh form of disease or the existence of impurities in the beer. The medical officer of health made an appointment with Dr. Reynolds to see the cases next day at Crumpsall. On visiting the Crumpsall Workhouse on Nov. 21st he saw, in company with Dr. Reynolds and Dr. H. G. Brooke, a large number of cases presenting special and fairly uniform symptoms. Dr. Brooke stated that he had seen for some time a number of cases with eruptions of a peculiar nature and such as to give rise ultimately to a suspicion of arsenical poisoning. The medical officer of health at once saw Mr. Rook, the superintendent of the Sanitary Department, and they arranged that 12 samples of beer (sixpenny and fourpenny from each) should be obtained from six tied houses. These samples were accordingly obtained and submitted to the public analyst. Meanwhile, Dr. Tattersall, the medical officer of health for Salford, had submitted samples of beer to Professor Delépine, who, in the absence of Professor Dixon Mann, undertook an investigation into the nature of these samples which had apparently given rise to symptoms of poisoning in Salford. Your medical officer of health could not move further in the matter until on Nov. 23rd Dr. Kelynack called to inform him that he and Dr. Kirkby had that day discovered the arsenic present in the beer to arise from glucose. On the same day Professor Delépine informed your medical officer of health that on Nov. 22nd he had discovered the presence of a considerable amount of arsenic in particular saccharine matters used in brewing, and that he at once communicated with Dr. Tattersall.

Dr. Tattersall on Nov. 23rd went down to Liverpool (as your medical officer of health was informed by a reporter) to procure a sample of the sulphuric acid used in making the incriminated glucoses and inverts. It did not appear to your medical officer of health necessary to obtain samples of the materials at that time from the glucose manufacturers, as these had already been procured by Dr. Tattersall at the earliest possible time, and the results of the investigation which he knew was being conducted by Dr. Tattersall with equal energy and skill would be available at an early date for our own procedures. It did, however, seem necessary to act with all possible speed administratively. On Nov. 23rd, therefore, samples of the saccharine materials employed were obtained from two breweries implicated by the patients. On Nov. 24th your medical officer of health improvised a laboratory in his room, aided by the assistant medical officers of health, Dr. Coates and Dr. McCleary, and by Mr. R. M. Rowe of the Sanitary Department, a gentleman of considerable chemical experience, whose services have been most valuable. Two samples of beer and one of stout were procured and examined on Nov. 24th. A trace of arsenic was believed to be found in a sample of beer, and the same material was believed to have been found in one of the saccharine matters. Your medical officer of health then consulted Professor Delépine who, with his usual courtesy and kindness, showed him the methods which he had employed and the quantities of the materials used in the analyses. On Nov. 26th the examinations were renewed at the office, and, being fortunate in the methods which we adopted for the Marsh test, on the 27th we were in a position to proceed. Samples of the saccharine matters stated to have been used by the brewers were rapidly obtained by the medical officers and we commenced an examination of all the saccharine matters furnished to us as being those in use by 23 Manchester breweries visited, as well as of three glucoses used in the manufacture of cheap sweets and jams. As regards the latter it may at once be said that not a trace of arsenic was found in them. As regards the saccharine matters which were furnished to us by the brewers as being used by them, and which included Home and American glucoses and inverts, we examined them all to the number of 46 specimens from 20 breweries. In not one did we find a trace of arsenic except in the glucoses and inverts emanating from one firm, in which it was present apparently in considerable amount. Unfortunately, five out of the 20 breweries were using this material to our knowledge, or had just discontinued it, while in another instance its use had been discontinued for two months. It is possible that there are other breweries in which it has been used where we have not been informed of the fact. As soon as we knew that the examination of a saccharine material revealed the presence of arsenic, information was sent to the manager of the brewery concerned with a request that all beer now on the market in which the incriminated sugar had been used should be immediately recalled.

Meantime on Nov. 27th a circular letter was sent to all the practitioners in the city asking for certain information, based on the symptoms of the cases at Crumpsall. The replies to these are most valuable and instructive. Basing our action on these reports and on the information which they afforded, and in pursuance of an instruction from the meeting of the Sanitary Committee of Nov. 27th, we have obtained samples from a number of public-houses. Instructions were given by the Sanitary Committee on Nov. 28th that this course should be pursued, and it is considered that ample opportunity has been given to get rid of any poisonous beer or stout. Some samples since taken from public-houses and examined unofficially have been found to contain an appreciable amount of arsenic. The number of samples of beer and stout examined unofficially since the instruction of the committee has been 45, of which 11 have been found to contain arsenic. Subsequent samples from the same houses have been sent to the public analyst.

After the exhaustive investigation carried out by Dr. Tattersall and Professor Delépine there remains very little to be said on the subject except on matters of detail. There are, nevertheless, some points on which the committee would probably wish to be informed, especially what has been the nature and magnitude of the evil.

Nature of the disease.—There is a class of disease known to medical men as alcoholic neuritis. As a few good observers state that they see no difference between these fresh cases and those which they have previously known as alcoholic neuritis this will sufficiently indicate the nature of the outbreak to medical men In the slighter cases there may or may not be nausea and sickness and irritation of the eyes, followed by a feeling of pins and needles in the tips of the fingers and toes; the calves are painful on pressure, and the hands presently become numb and useless. Wasting of certain small muscles of the hand is almost invariable. Many cases get dropped wrist or walk unsteadily. In the most severe cases the paralyses advance quickly, the patient cannot stand, has perhaps delirium, and sinks into a comatose state from which he does not recover. A prominent feature of many of the cases is pigmentation of the skin, which in some cases has been very deep, the patient being almost like a mulatto.

It is impossible in a report of this kind to do more than indicate the kind of illness to which our figures relate, although the courtesy of the medical officers at Crumpsall and Withington in allowing the medical officers to see the cases must be acknowledged. The medical officer of health has received information of about 1000 cases of the above class of illness from 90 medical men. These do not include the cases which have been sent into the union hospitals during the last few months which will probably come to 700 or so more. Allowing over 300 cases to medical men who have not answered the circular there have thus been at least 2000 cases who have been seen by a medical man. There will, no doubt, be a good many more with minor degrees of illness which have not been seen by a medical man.

An important question is whether there is any appearance of improvement in the outbreak. Many medical men state that the cases still continue to come in, as they will do for a little time even if the incriminated beer is entirely stopped, since it takes some time to produce the wasting observed in these cases. The general impression conveyed by the statements of medical practitioners is that the worst has passed and that the worst period of all was towards the end of October. What do our statistics say? The statistics should throw some light on the question whether this is or is not an entirely new phenomenon, and I have, therefore, had the deaths excerpted week by week under these headings: peripheral neuritis; neuritis; alcoholism; cirrhosis of the liver; other disease of the liver; gastritis in adults. These deaths are then added up to make a total for the week. The result is shown on the table given on the previous page and the figures are sufficiently remarkable.

The number of total weekly deaths from the enumerated causes suddenly shoots up in the last week of May and thenceforward, generally speaking, remains high up to the present time. We may suspect that some alteration took place in the quality of the beer used about the beginning of May. This we have not yet time to inquire into. The same period—viz., the end of May—also marks a slight increase in the number of deaths ascribed to peripheral neuritis, which now furnishes about one death a week. Yet even in the last two weeks of September no death is ascribed to this cause. In October, however, there is a very slight increase, sufficient at all events to show that some observers were now becoming alive to the character of the cases. We may at the same time confidently assume that, in the absence of this suspicion, most of the few cases added to peripheral neuritis in October would have appeared in the column alcoholism. This your medical officer of health has ascertained both as the result of conversations and *from* the reports sent in.

How do the figures of 1900 compare with the figures for a corresponding period of 1899? The deaths from peripheral neuritis have nearly doubled in 1900. The difference is, however, confined to recent months, since up to the end of May there were in 1900 only five deaths from this cause, as compared with eight in 1899 from Jan. 1st to May 31st. Many medical men have regarded this outburst as an outbreak of alcoholism due to the war fever. It is therefore of considerable interest to see whether in 1899 there occurs any change in the number of deaths from the causes enumerated similar to that which appears in the present year. It will be seen from the table that the figures for July and August of 1899 seem to indicate a similar increase of this class of case on a smaller scale, the increase being observable under both alcoholism and cirrhosis of the liver. These figures suggest to your medical officer of health that the recent occurrence does not stand quite alone and that previous mischief in connexion with alcohol has occurred in an epidemic fashion. The suggestion is that there may have been arsenic present in the beer formerly. There is, indeed, reason to suspect that the same phenomenon may have been going on for years, though in a slighter degree. This would justify some delay in recognising the nature of the disease, since the cases would be regarded as ordinary alcoholic cases of a recognised type with an unusual proportion of certain striking though not unknown features.

Tables have also been prepared for 1897 and 1898 and the results may be thus summarised :—

Causes of death.	Number of deaths in the first 48 weeks of			
	1897.	1898.	1899.	1900.
Peripheral neuritis	11	17	18	39
Neuritis (other)	2	5	5	11
Alcoholism	71	43	77	98
Cirrhosis of the liver	88	76	88	105
Other diseases of the liver...	35	32	17	20
Gastritis (adults)	25	32	9	19
Total	232	205	214	292

There has, therefore, not been much change in the aggregate number of deaths in 1897 to 1899, while it has greatly increased in the present year (1900). There has been an increase year by year since 1897 in the number of deaths from peripheral and other neuritis, very much accentuated in 1900. The deaths from alcoholism have increased progressively since 1898, and in 1900 are more than double the number in 1898. They were, however, more numerous in 1897 than in 1898. The number of deaths from cirrhosis of the liver have increased progressively since 1898. In 1897, however, they were more numerous than in 1898. From other diseases of the liver than cirrhosis the number of deaths was greater in 1897 and 1898 than in 1899 and 1890. From gastritis the same relation very singularly holds, with the addition that the deaths in 1900 number more than twice as many as those in 1899. The far larger number of deaths from alcoholism and cirrhosis of the liver in 1897 than in 1898 taken along with their distribution in weeks is striking and calls for future inquiry. On the whole, the complete figures do not remove the impression that this is not an entirely new phenomenon.

In accordance with the instructions of the Sanitary Committee a vigorous search is being made for arsenical beers and stouts sold in public-houses, and suspected samples have been submitted officially to Mr. Estcourt. It is desirable that a quantitative analysis should be made for one of these samples, but it is probable that the qualitative tests carefully carried out will suffice for a prosecution under the Food and Drugs Acts. Still, one quantitative analysis is advisable.

To the assistant medical officers, Dr. Coates and Dr. McCleary, I am indebted for the accounts of individual cases which they have collected and for the pains which they have taken to collect facts. Mr. R. M. Rowe of the sanitary department has conducted the qualitative analysis of samples with his usual care and skill and with ungrudging zeal. My statistical clerk, Mr. Ross, has prepared the statistical tables which have entailed considerable labour.

THE WAR IN SOUTH AFRICA.

NOTWITHSTANDING the assurance of Lord Roberts that the war is over it cannot be said that Boer resistance has ended or that there is any immediate prospect of its being ended. The war has, as we all know and regret, degenerated into a desultory kind of marauding and surprises, varied by vigorous and exhausting pursuits of De Wet. As a rule, the efforts of the British to repel the attacks of the more or less disorganised and scattered bodies of Boers acting independently of one another have been very successful, but it is still far from being the fact that all dangerous opposition has been stamped out. Lord Roberts has resigned his command in South Africa and has handed it over to Lord Kitchener, who is generally thought to be admirably suited to deal with the present phase of the war and to bring it to an end. It will be remembered that while in a military sense the conquest of Burma proved a comparatively easy task, the real subjection of that country and the suppression of the system of dacoity was a very difficult one, and the Boers are a very different and far more tenacious foe than the Burmese. Such is, briefly summarised, the present position of affairs in South Africa. The capture of that redoubtable warrior and clever tactician De Wet and his force, whenever it is accomplished, will probably have a decisive effect The description of the recent chase of De Wet is of the most exciting kind and says a great deal for the pluck and endurance of the troops on both sides No better illustration could be given, by the way, of the very difficult and puzzling problem of safeguarding the health of troops on service by sanitary measures than is afforded by these forced marches It is not easy to see what plan of hygienic precautions could be devised for the purpose, and it is likely that any recommendations on the part of the medical service would be, and from the emergent nature of the case probably would have to be, practically disregarded Such occurrences must, we fear, often take place in war where it is all that troops can do to carry their food supplies and ammunition Setting aside, however, such exceptional conditions, it seems to us that we may in future wars have to organise a special sanitary corps with a large and properly directed executive service and furnished with all necessary appliances for field sanitary work

Turning to matters of more immediate medical interest we have to note that Lord Stanley, writing from headquarters in South Africa, has replied to a letter by Mr Burdett-Coutts dated Sept 19th last in which the latter challenged the correctness of Lord Stanley's evidence before the Royal Commission Lord Stanley adheres to his original statements and inferences, and by way of corroborating them accompanies his letter with one from Mr W Maxwell, a correspondent of the *Standard* Mr Burdett-Coutts, however, replies at some length in the *Times* to Lord Stanley, repudiating the notion that he had ever used or intended any covert threat as alleged It is a lively little episode, but it has no real bearing on the facts regarding the state of the hospitals —at least none of public interest as it seems to us According to Mr Balfour's statement in the House of Commons, in reply to Sir Walter Foster, the Royal Commissioners hope to present their report on the South African hospitals early in the ensuing year and we may therefore be content to await its publication The figures showing the amount of sickness attributable to typhoid fever during the campaign are heavy Mr Powell Williams stated in the House of Commons on Dec 11th that the total number of cases of typhoid fever amongst the forces in South Africa from the beginning of the war till Sept 28th last was 15,655, and the number of deaths from that disease was 3642, and that the number sent home as invalids was 9128 Mr Brodrick has promised in the House of Commons to give the fullest consideration to the report of the Hospitals Commission He pledged himself, moreover, to make such changes, however radical as would be likely to make an efficient army medical service The Queen and the Royal Family have always manifested a great interest in all that concerns the sick and wounded soldier, and it was only to be expected that the Princess of Wales would visit Southampton in order to welcome home the invalids and wounded arriving in this country on board the hospital ship named after Her Royal Highness This being the third voyage in this particular service made by the vessel a statement was handed to the Princess during her visit setting forth the important services which the ship had performed during the year of her employment for hospital purposes

THE IMPERIAL YEOMANRY BASE HOSPITAL

By L V. CARGILL, F.R C S.,

OPHTHALMIC SURGEON TO THE HOSPITAL.

To day (Nov 10th) there are 492 patients in the hospital—viz, 16 officers and 476 non commissioned officers and men Of these nine officers and 362 non commissioned officers and men (i e, nearly four fifths) belong to the Imperial Yeomanry We are becoming almost entirely a Yeomanry Hospital in deed as well as in name, for although we have not received hospital trains for the last few weeks Yeomanry are arriving from the front daily in tens and twenties They come down by the ordinary trains and are mostly convalescent and recovering from fever contracted further north In response to the diminution in the work there has been a further reduction in the staff Dr J W Washbourn has transferred his services to the branch hospital at Pretoria, where he was much needed, I myself am just leaving for home; whilst Dr J B. Christopherson and Mr W O G Ashdowne, as well as several nursing sisters, have already left

On the surgical side Mr H A Ballance has operated on several cases of appendicitis lately with satisfactory results In some of these an abscess had formed and in others the appendix was removed in the quiescent interval, the hardships of the campaign causing the old disease to be again active A case of typhoid fever with perforation was operated on recently The patient, a man, aged 30 years, was under the care of Dr A Elliot, and perforation occurred in the fourth week of the disease, which was severe and marked by much toxæmia Distension was not great At the time of perforation the pulse was 96 and the temperature was 101 2° F There was no fall of temperature with the perforation, although the pain was sudden and was severe enough to make the patient call out and to double him up in bed During the next few hours the temperature gradually rose to 102 6° and the pulse to 116 Tenderness and rigidity increased to the lower half of the abdomen Mr Ballance operated within six hours of the attack of pain and found that there was perforation immediately under the laparotomy wound in a coil of the ileum 18 inches from the cæcum It was one sixteenth of an inch in diameter and there had been very little leakage into the abdominal cavity The aperture was closed by eight Halsted silk sutures, quite half an inch of the wall of the bowel being infolded on each side of it As a precautionary measure a few stitches were placed in another Peyer's patch, 12 inches from the cæcum, to infold its very thin base The intestinal coils and Douglas's pouch were sponged dry No irrigation or drainage was used The patient progressed extremely well for the next 48 hours the pulse coming down to under 90, the temperature was subnormal, there was no pain, and it was thought that he would pull through At the end of this time, however, he again complained of abdominal pain, distension came on rapidly, the temperature rose to 102 6°, the pulse to 144 and he died in 56 hours from the time of the operation There was no vomiting either at the time of the initial perforation or subsequently At the necropsy it was seen that another minute perforation had occurred through the base of the same ulcer as before along the track of one of the sutures and had caused the second attack of peritonitis The whole of the Peyer's patch, which was a very wide one, had not been infolded at the operation, as too much narrowing of the lumen of the bowel was feared There was extensive ulceration in the lower three feet of the ileum and also in the cæcum It is to be regretted that of the three cases of perforation in enteric fever operated on in this hospital not one has recovered A case of abscess of the liver resulting from a Mauser bullet which traversed the right lobe of the organ has occurred The patient is rapidly recovering since the operation, but as the recovery is not yet complete details of the case must be left to a subsequent report Too much praise cannot be accorded to Mr Hall Edwards for the admirable way in which the x ray department has been managed and the absolute certainty of localisation to the smallest fraction of an inch that has attended his work on the radiography of foreign bodies lodged in the tissues

On the medical side there is not much of importance to record Enteric fever has been decidedly on the increase during the last month and a number of cases have come down from the front either with signs of the disease or in the incubation stage but none has been contracted in hospital The general type of disease is less severe than formerly, which is due, no doubt, to the better condition and therefore greater resisting power of the men One of our dressers (Mr A C Ransford) is at present suffering from enteric fever, contracted in all probability in Pretoria So far the disease is running a mild course With regard to the cases of enteric fever the frequency of phlebitis in the convalescent stage is to be particularly noted The frequency of this complication here is considerably greater than in ordinary civil practice Suppurative otitis media is also far from uncommon In two cases complicated with malaria the tertian parasite has been demonstrated as well as Widal's reaction A few cases of acute dysentery and many of chronic dysentery have been admitted and all the patients have done well Experiments are now being carried out with various native remedies in the treatment of dysentery, hitherto with no very striking results, but the cases have been comparatively few in number A fuller report will follow at a later date

No fresh case of scarlet fever has developed in hospital for over four weeks Suspicious cases, and a few in which the diagnosis is beyond suspicion, still continue to be admitted. Cases of heart and renal disease have increased in number to a considerable extent since the last report. Of the former a few are instances of valvular disease arising during an attack of acute rheumatism, but the majority are examples of failure of compensation due to the strain of hard work and exposure on an already damaged heart. To the same causes our cases of acute kidney affection can be traced. Rheumatism, especially the subacute articular and muscular varieties, is still very common. It is interesting to note that in the great majority of the former and in many of the latter there is a history of previous acute rheumatism. Acute rheumatism is, and has been, conspicuous by its absence, though many patients convalescent from the disease have been admitted. Dr. Elliot remarks that from what he has seen here he would be inclined if examining men for war purposes to reject all, or nearly all, those who have passed through an attack of rheumatic fever. The selection of men for the Yeomanry battalions has apparently been made on specially liberal lines. Many cases of old-standing valvular and renal disease have come out and one man arrived in hospital with an unhealed nephrotomy wound with which he had left home. Other patients have come under my own care who have been passed and sent out for active service in the field, the condition of whose eyes and sight should have led to their rejection.

Deelfontein, Nov. 10th.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Annual Report of the Medical Officer of St. George-the-Martyr, Southwark, for 1899.—The population of the above metropolitan parish at the last census showed a low rate of increase compared with that of London generally. That fact is accounted for by the disproportionate mortality and not by the birth-rate, which in 1899 was 5·8 per 1000 above that for the whole of London and 5 per 1000 above that for the 33 large towns. The total population of the parish at the last census in 1896 was 60,278, as against 59,712 in 1891. In 1899 the population density of St. George-the-Martyr was rather over 213 to the acre, that is to say, about four times that of London generally, and 400 times that of the United Kingdom. The death-rate for 1899 is abnormally high, being 27·7 per 1000 living. Analysis shows that the brunt of the mortality falls upon the Borough road sub-district, in which the rate was 34·8 per 1000, as against 23·5 for the London-road and 26·6 for the Kent-road sub-districts. Further, the average for the years 1892 to 1896 in those sub-districts showed the Borough-road rate to be 31·4 per 1000, compared with London-road 20·6 and Kent-road 22·3. This interesting method of analysis leads Dr. F. J. Waldo to remark: "Were it possible to eliminate the Borough sub-district or to reduce its mortality to a level with that of the other sub-districts the condition of St. George-the-Martyr as a whole would compare favourably with many districts much more happily situated, both as regards density of population and general happiness of surroundings." In the ten years 1841 to 1850 the average death-rate of the parish stood at 30 per 1000, as against 25 for the whole of London. In 1899 it was 27·7, against 19·3. For last year, indeed, St. George-the-Martyr stands in a worse position with regard to the London death-rate than it has stood in any ten-yearly period since 1840. Diarrhœa has been answerable for more deaths than any other of the principal zymotic diseases during the eight years 1892 to 1899. Dr. Waldo's conclusion as to the origin of this malady, announced in the Milroy lectures for 1900, attributed the infection to contamination of food, air, and general environment of towns by street-dust specifically contaminated by bacteria from horse-dung. In connexion with the recent outbreak of enteric fever in the parish it is interesting to note that in March, 1898, Dr. Waldo urged the vestry to establish a free bacteriological service for the early diagnosis both of typhoid fever and of diphtheria. In neither case has the recommendation been acted upon. The report before us will be notable in the history of the ancient parish of St. George the-Martyr, as it represents the last official year of separate existence as a local authority. The opportunity has been taken to draw up a short summary of progress in public health matters that has been made during the seven years and seven months of Dr. Waldo's tenure of office. Disinfection is now carried out by means of a steam disinfector of the best modern type, the special staff has been increased, and a shelter has been provided for infected families. Lavatory accommodation has been greatly increased. A large number of houses unfit for human habitation have been closed and a large unwholesome area, that of Falcon court, has been dealt with by the London County Council. The sanitary staff has been increased from two inspectors and a third officer, who acted as mortuary-keeper and disinfector, in 1892, to one chief and three district inspectors, two women inspectors to carry out the tenement by-laws, two caretakers of the Reception House, and a sanitary clerk. This staff is still inadequate for so large and crowded a parish. The important question of the sanitary control of the Salvation Army shelters by the local authorities has to a great extent been fought out in Southwark. In 1890 the late Lord Coleridge decided that the Salvation Army shelter was not a common lodging-house. In 1893 small-pox was traced to the Blackfriars shelter, the keeper of which was prosecuted by the St. George's authority for neglecting to disinfect. The magistrate convicted, but his decision was reversed on appeal. In this way it was shown that efficient disinfection could not be insisted upon under the Public Health Act. In 1895 small-pox was again traced to the shelter, but the medical officer of health having been refused admission at night obtained entry later by a magistrate's warrant. The question thus opened up was carried to its conclusion by the London County Council in 1898. On appeal in December, 1899, the High Court of Justice decided that the shelters were common lodging-houses and therefore were subject to public sanitary control. Among the special reports is an interesting one dealing with a case of typhus fever and its origin. The original case was notified on Feb. 20th, 1899, and was found to have come from Bermondsey. In the previous year two cases of typhus fever, one in April and one in October, had occurred in the parish of St. George-the-Martyr, and some members of one infected family, the second case, had gone to Bermondsey. Careful inquiry revealed a direct chain of infection between the case in October, 1898, and the case in February, 1899. At least 12 cases were found; they had been treated at various hospitals and at home for enteric fever, delirium tremens, and other supposed maladies, but only in one or two instances was the typhus fever recognised at the time. This record is suggestive in many ways and emphasises the rarity of the disease nowadays in the metropolis. The medical officer may be congratulated upon the amount and the degree of good work accomplished since he has held his official post in the parish. In the matter of the control of bakehouses, especially when underground, he has been specially active, and his reports, no doubt, influenced the legislation that has been enacted within the past few years in that direction.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6082 births and 3937 deaths were registered during the week ending Dec. 8th. The annual rate of mortality in these towns, which had risen from 16·9 to 18·0 per 1000 in the four preceding weeks, declined again last week to 17·7. In London the death-rate was 17·5 per 1000, while it averaged 17·8 in the 32 provincial towns. The lowest death-rates in these towns were 11·5 in Croydon, 11·8 in Cardiff, 13·6 in Portsmouth, and 14·4 in West Ham; the highest rates were 21·2 in Sunderland, 21·5 in Sheffield, 21·9 in Liverpool, and 22·1 in Hull. The 3937 deaths in these towns included 363 which were referred to the principal zymotic diseases, against 351 and 356 in the two preceding weeks; of these, 98 resulted from diphtheria, 91 from whooping-cough, 55 from "fever" (principally enteric), 51 from measles, 35 from scarlet fever, and 31 from diarrhœa. No death from any of these diseases occurred last week in Birkenhead, Huddersfield, or Gateshead; in the other towns they caused the lowest death-rates in Croydon, Sunderland, and Newcastle, and the highest rates in Swansea, Blackburn, Preston, and Sheffield.

The greatest mortality from measles occurred in Swansea; from scarlet fever in Burnley; from whooping-cough in Nottingham, Derby, Preston, Halifax, and Hull; from "fever" in Plymouth, Wolverhampton, and Preston; and from diarrhœa in Blackburn. The 98 deaths from diphtheria included 34 in London, 14 in Sheffield, eight in Leeds, and eight in West Ham. No fatal case of small-pox was registered last week in any of the 33 towns, and only one small-pox patient remained under treatment in the Metropolitan Asylums hospitals on Saturday last, Dec. 8th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2687, against 2725 and 2727 on the two preceding Saturdays; 259 new cases were admitted during the week, against 261, 246, and 279 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 322 and 436 in the two preceding weeks, declined again last week to 400, and were 48 below the corrected average. The causes of 56, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Oldham, Leeds, Sunderland, and seven other smaller towns. The largest proportions of uncertified deaths were registered in Leicester, Liverpool, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 19·2 to 21·7 per 1000 in the four preceding weeks, declined again last week to 20·7, and showed an excess of 3·0 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17·2 in Leith and 17·4 in Dundee to 21·9 in Perth and 23·1 in Edinburgh. The 641 deaths in these towns included 31 which were referred to whooping-cough, 18 to diarrhœa, 15 to measles, nine to scarlet fever, nine to diphtheria, four to "fever," and one to small-pox. In all 87 deaths resulted from these principal zymotic diseases, against 69 and 89 in the two preceding weeks. These 87 deaths were equal to an annual rate of 2·8 per 1000, which was 1·2 above the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had increased from 13 to 42 in the eight preceding weeks, declined again last week to 31, of which 18 were registered in Glasgow and five in Greenock. The deaths from diarrhœa, which had been 20 and 19 in the two preceding weeks, further declined to 18 last week, and included six in Glasgow, three in Edinburgh, three in Dundee, and three in Aberdeen. The fatal cases of measles, which had been eight and 12 in the two preceding weeks, further rose last week to 15, of which nine occurred in Edinburgh and four in Aberdeen. The deaths from scarlet fever, which had been five in each of the two preceding weeks, increased to nine last week, and included five in Glasgow and three in Edinburgh. The fatal cases of diphtheria, which had been four and six in the two preceding weeks, rose last week to nine, of which five were registered in Glasgow, two in Edinburgh, and two in Aberdeen. The four deaths referred to "fever" corresponded with the number in the preceding week, and were all recorded in Glasgow, where the fatal case of small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 156 and 160 in the two preceding weeks, declined again last week to 151, and were slightly below the number in the corresponding period of last year. The causes of 25, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·1 and 24·5 per 1000 in the two preceding weeks, rose again to 27·4 during the week ending Dec. 8th. During the past four weeks the death-rate in the city has averaged 26·0 per 1000, the rates during the same period being 17·4 in London and 20·3 in Edinburgh. The 184 deaths belonging to Dublin registered during the week under notice showed an excess of 20 over the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 19 and 11 in the two preceding weeks; of these, four were referred to whooping-cough, three to "fever," three to diarrhœa, and one to scarlet fever. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·5 in London and 3·3 in Edinburgh. The fatal cases of whooping-cough, which had been five and six in the two preceding weeks, declined again to four last week. The deaths referred to different forms of "fever," which had been eight and three in the two preceding weeks, were again three last week. The fatal cases of diarrhœa, which had been five and one in the two preceding weeks, rose last week to three. The 184 deaths in Dublin last week included 41 of infants under one year of age and 45 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed an excess over the numbers recorded in the preceding week. Four inquest cases and four deaths from violence were registered, and 64, or more than a third, of the deaths occurred in public institutions. The causes of 18, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: Walter H. S. Stalkartt to the *Alacrity*; Hugh S. Burniston to the *Duke of Wellington*, additional for Portsmouth Dockyard; H. W. W. Townsend to the *Blenheim*; and E. T. Meagher to the *Briton*.

Fleet Surgeon Henry L. Crocker, of the *Britannia*, medical officer of the Naval Cadets' Training Establishment, is selected for appointment to the *Royal Arthur* when recommissioned as flagship of the Australian station.

ROYAL ARMY MEDICAL CORPS.

Major Fausset Maher Baker retires on retired pay.

MILITIA.

Royal Garrison Artillery: The Mid Ulster Artillery (Southern Division): Surgeon-Lieutenant-Colonel W. Twigg retires under paragraph 81 Militia Regulations, with permission to retain his rank and to wear the prescribed uniform on retirement.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major A. Kinsey Morgan resigns his commission.

VOLUNTEER CORPS.

Artillery: 2nd Devonshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant-Colonel J. May resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. 1st Warwickshire: The undermentioned officer is removed from the Volunteer Force, Her Majesty having no further occasion for his services:—Surgeon-Lieutenant S. P. Johnson. *Rifle*: 4th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant-Colonel W. S. Limrick resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 8th (Scottish) Volunteer Battalion the King's Liverpool Regiment: Archibald Gordon Gullan to be Surgeon Lieutenant. 1st Lanarkshire: James Grant Andrew to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Vernon John Greenhough to be Surgeon-Lieutenant. *17th (North) Middlesex*: The undermentioned Surgeon-Captains resign their commissions:—P. S. Spokes and J. W. Pare. *16th Middlesex* (London Irish): Surgeon-Captain A. G. Bateman resigns his commission.

TRANSVAAL WAR NOTES.

Mr. Vernon Cargill has returned to England after an absence of ten months, during which time he has served as ophthalmic surgeon to the Imperial Yeomanry Hospital in South Africa.

Civil Surgeons R. Ward, A. Broslin, C. Gibbs, H. J. Scharlieb, and W. W. Woolliscroft have returned invalided to England in the transport *Yorkshire*. Civil Surgeon Gordon Watson is returning home in the *Carisbrooke Castle*. Civil surgeons E. A. Nathan, E. M. Pearse, and A. N. Weir left South Africa on Dec. 6th in the *Manhattan*.

The Princess of Wales went to Southampton on Dec. 10th to visit the hospital ship bearing her name, which arrived from the Cape on Dec. 8th with 170 invalids in charge of Captain A. Pearse, R.A.M.C. Her Royal Highness briefly conversed with all the patients.

Civil Surgeon H. Hartley (Lovat's Scouts) is reported convalescent at Cape Town.

THE SPECIAL ARMY ORDER REWARDING THE TROOPS.

A special Army Order has been promulgated from the War Office to the effect that the Secretary of State has decided that a special war gratuity should be issued to all the troops, whether Imperial or Colonial, employed in the operations in South Africa The unit of the scale will in all cases be £5, which will, therefore, be the minimum sum to which any soldier will be entitled. A table setting forth the number of shares or units assigned to the different ranks—from that of a Field-Marshal downwards—together with an explanatory statement, is published for general information, so that everybody concerned can calculate the amount of the gratuity to which he is entitled. The total, considering the numbers who have taken part in the war, will reach a good sum, but the taxpayer, instead of grudging the outlay, will, we believe, pay it with a hearty goodwill. It has been well earned, for it has been a most arduous and trying war from start to finish—that is when it is actually as well as virtually finished. Lord Roberts has told the nation his opinion of the troops who have served under him—namely, that the soldier was a hero in the battlefield and a gentleman elsewhere. In addition to all the fighting there has been an unprecedented amount of marching, and no one can have read the description of what the troops had been undergoing in their last chase of De Wet without realising the labour and hardships which this war has entailed. It has proved the very opposite of what was once a popular affix to the signboards of hotels and country inns—"good entertainment for man and beast." We trust that has yet to come for all our soldiers and medical and other officers who have suffered the risks and fatigues and who survive all the dangers of this war.

MENTIONED IN DESPATCHES.

Sir Claude MacDonald, in his despatches relating to Pekin, refers to Dr. Morrison, the *Times* correspondent, who acted as lieutenant to Captain Strouts and rendered most valuable services. He was, says the despatch, active, energetic, and cool: he volunteered for every service of danger and was a pillar of strengh when matters were going badly. He was severely wounded on July 16th by the same volley which killed Captain Strouts, and his valuable services were lost to the defence for the rest of the siege. The services of Dr. Poole, Legation surgeon, and Dr. Velde of the German Legation, are also referred to. These gentlemen were in charge of the International Hospital, and during the siege 166 cases passed through their hands, 20 of the patients suffering from illness and the rest severely wounded. Owing to the devotion and skill of these two medical officers 110 of the wounded were eventually discharged cured, notwithstanding that towards the end of the siege, the resources of all the dispensaries proved unequal to the strain. Dr. Poole, continues the despatch, speaks most highly of the sick-berth steward, Fuller, of Her Majesty's ship *Orlando*, and his commendation is fully endorsed by Dr. Velde and all the besieged. From personal observation Sir Claude Macdonald says that his care and gentle treatment of the wounded and the willing and cheerful manner in which he carried out his duties were beyond all praise.

THE SYRACUSA CONVALESCENT HOME FOR WOUNDED SOLDIERS, TORQUAY.

At a meeting of the subscribers of the Syracusa Convalescent Home held at Torquay on Dec 5th it was stated that since the opening of the home at the beginning of the year 127 soldiers had been admitted representing 50 different regiments. During the five months July to November the average daily number of patients were 31, and the average weekly cost per head was 8*s.* 3*d.* The credit balance at the end of November amounted to £1730. Colonel Stovell, the honorary secretary, said that the conduct of the men had been splendid. In the words of Lord Roberts their bearing had been that of heroes and their manners those of gentlemen. Colonel Stovell further alluded to thoughtless people who gave the soldiers drink, and quoted a case where a person gave a man a bottle of brandy which he was urged to hide in his bedroom in case he felt ill and needed it, the result being that the man became mad with drink and threatened to commit suicide.

OUR LOSSES IN SOUTH AFRICA.

According to a War Office return the total reduction of the military forces through the war in South Africa up to, and inclusive of, November has amounted altogether to 14,178, of which number considerably under 12,000 have been from deaths—either killed in action or from wounds or from disease contracted on service. Looking to the duration of the war, the numbers engaged, the continuous fighting of some sort or other and somewhere or other in the theatre of war, and other circumstances, these figures do not seem so large as might have been expected.

THE PASTEUR INSTITUTE AT KASAULI.

This institute, which has been recently opened at Kasauli under the management of Major D. Semple, R.A.M.C., for the Pasteur treatment of soldiers and others, is, we are glad to say, popular and is apparently doing a great deal of good. Up to Nov. 4th last 75 patients had presented themselves for treatment and 62 had completed their course, while 13 were under treatment. The 75 patients comprised seven British officers, 25 soldiers, and one soldier's child, one native officer, four native soldiers, 12 European civilians, and 25 native civilians.

ST. JOHN AMBULANCE ASSOCIATION.

The St. John Ambulance Brigade is despatching 100 more hospital orderlies for service in South Africa, having received a further requisition from the War Office to that effect. This is in addition to the 68 extra brigade men dispatched a fortnight back at Lord Roberts's request, and brings the total of its members on active service up to 1739. Over 60 members of the brigade have, we regret to say, died from enteric fever and other diseases.

DEATHS IN THE SERVICES.

Surgeon-General G. V. Currie, late I.M.S., in London, on Dec. 3rd, aged 72 years. He served in the Indian Mutiny campaign against the Momunds on the North-west Frontier in 1858, in the Eusofzai and Swat Expedition of 1866, and in the Afghan War of 1879.

Captain William Pearson Barter, R.A.M.C., at Agra, aged 34 years. He was the only surviving son of Brigade-Surgeon J. F. Barter (retired), of Beneden, Harlesden N.B. He joined the Army in 1893 and became Captain in 1896.

John Grant, M.B., C.M. Edin., has been appointed temporary surgeon to H.M. forces now operating in Ashanti.

Correspondence.

"Audi alteram partem."

NEW-LAID EGGS AND FRESH EGGS.

To the Editors of THE LANCET.

SIRS,—In the interesting annotation which you have given us on the "new-laid" and "fresh" egg question, arising out of the recent correspondence in the *Times*, you have not (any more than the *Times* correspondents) given scope to a solution of the difficulty which certain early recollections of my own lead me to believe deserves more attention than has been hitherto assigned to it. I admit that the "trader" and his conventional nomenclature (with a view to charges and profits) has no part in my experiences, which centre round a very dear old relative long since passed away, who in my boyhood used to supply us with "fresh" eggs on a system of her own—not unknown indeed to others, but practised by her with a carefulness which gave it a place quite apart from commercial experience Her plan was simply to grease all her eggs—not, observe (for to this she attached great importance), within the first 24 or any number of hours, but *the instant they were laid and before they had time to cool.* The pores of the egg being thus effectually sealed up before any chemical change had time to take place, the practical result, as I have tested over and over again, was that the eggs remained "fresh" (by which I mean that they retained the creamy quality of the albumen to which you refer), not for hours or for days, but for weeks and, I believe, for months, during which the eggs, though not "new-laid," were emphatically as "fresh" to the taste as if they had been eaten an hour after being laid. This I know to be the fact because it was one of this old lady's business-like ways that on an immensely long egg-rack she had every egg marked with the date of laying at the very moment of its being submitted to her preservative process; and although I do not claim to have investigated the matter scientifically, I do know as a fact that an egg, say, three weeks or six weeks old as by date, could absolutely not be distinguished by the taste from one laid only the day before, or even on the same day, as it was served up to breakfast. I have often wondered that my dear old relative did not make a more definitely "trading" use of her system, or that no other more commercial genius followed in her footsteps and boldly placed upon the market eggs which, though not "new-laid," were "fresh" in the best sense of the word. The system, indeed, required constant watchfulness, for if the egg was allowed to cool the chance was lost. But it should not be beyond the resources of a company of poultry-farmers to supply London with eggs guaranteed to be "fresh"—and only such—without reference to the exact date, the fact of freshness being tested as you describe, by the "ooscope" or otherwise. In short, if it is possible to preserve eggs indefinitely in the way here described it should be done, and all the resources of science should be applied to getting it done properly and securely. A company which could at once make *sure* that *all* eggs which it placed upon the market, independent of date, were fresh in the sense described might ask the highest prices and would be certain to get them, because the eggs would not need classification. I am, Sirs, yours faithfully,

Edinburgh, Dec. 10th, 1900. W. T. GAIRDNER.

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—It is to be feared that the readers of your valuable journal will gather from your remarks that I have merely expressed an opinion which may be met by the expression of an opposite opinion. If a system is not to be judged by results, by what standard shall we measure it? But if it may be so judged, then I claim that I have brought the failure of the isolation hospital, so far as scarlet fever is concerned, to an absolute demonstration. Being no great believer in statistics, there are yet, I hold, certain figures which are inexorable. The "returns" of the Registrar-General and the annual returns of the number of notified cases of medical officers of health cannot be ignored. On these, and these only, I have made out my case, and with deep respect for your opinion it is, I submit, a case which will have to be answered, and authoritatively answered. You place before your readers three reasons—which I can only regard as three excuses—for the existence of these hospitals—namely, (1) to minimise the risk of infection from invaded houses to the rest of the community; (2) to enable the sick to be separated from the healthy and the healthy to proceed to their occupations; and (3) to provide for better medical control and nursing than is possible in the homes of the poor.

With reference to the last position I may say at once that the isolation hospital is a preventive institution or nothing. It was certainly never designed to be a mere nursing institution for the poor. Had it been so intended it would have taken its proper place under the ægis of the Poor-law. As a matter of fact, the rich have frequently been admitted to whatever its advantges may be, to the exclusion of the poor. It is an entirely new reading of the ends and aims of isolation hospitals to include better medical attendance and nursing amongst the objects to be attained. With reference to the first position, I say that the risk from invaded houses has *not* been minimised, but, on the contrary, has been increased by "return" cases. We have all seen examples of houses being kept centres of infection for many months from this cause.

I have long held the opinion—take it for what it is worth—that discharged patients are *all* a source of danger to the community and that the period during which they remain in an infective condition is extended far beyond the limits of time exhibited by cases nursed at home, be the surroundings what they may. The definition of a "return" case has successfully covered up the formidable public danger which these cases undoubtedly constitute. I have a list of 250 cases which received their infection through the medium of a hospital, many of which were treated in the hospital itself, but only a dozen of which appeared in the annual report as "return" cases. I have called attention to the high mortality rate of "return" cases, as pointed out by Dr. C. K. Millard, Dr. P. Boobbyer, and others. As to the second position, if you are unable to guarantee freedom from infection on discharge from the hospital what becomes of "enabling people brought in contact with the patient to go to work, school," &c.? You know that this cannot be guaranteed. No secret is made of the fact. Here is the handbill sent to the friends of patients admitted into our isolation hospital:—

NOTTINGHAM CORPORATION. BAGTHORPE HOSPITAL. SCARLET FEVER.

To Parents, Guardians, and Others.

Although every care is exercised to prevent the carriage of infection by persons discharged from Bagthorpe Hospital it is impossible in some instances to insure against such an accident, for no one can say with certainty how long scarlet fever may lurk in the system Parents and others are warned against allowing recently discharged patients to come into unnecessarily intimate contact with others. No person discharged from a fever hospital should be allowed to sleep in the same bed as another until at least a fortnight after discharge. A short holiday in the country with plenty of fresh air, apart from others, is always desirable after convalescence from scarlet fever. But all persons recovering from scarlet fever should be warmly clothed and otherwise protected against cold. Any recently discharged person who complains of sore throat, nose, or ears, or who has a breaking out on the skin, should be at once isolated and placed under the care of a medical man In any case the corporation cannot accept responsibility or liability for the outbreak of infection occurring among the companions of persons recently discharged from hospital.

PHILIP BOOBBYER, M.B., Medical Superintendent.

One of the leading sanitarians in this country wrote to me last week saying that he could not conceive a more humiliating or tragic confession. Nor can I. When sanitary authorities hold out such danger signals as these surely the time has arrived to investigate, and if the investigation results in the accumulation of evidence which points to complete and universal failure, shall we ignore it? If it is proved that to aggregate cases of infective disease means the spread of disease, are we, as scientific men, under any pretext whatever to seek to excuse the carrying out of a system which has thus been weighed in the balance and found wanting? We know that it is happening every day that discharged patients are sowing scarlet fever broadcast in schools and elsewhere. You attribute this to defective administration. I am of a different opinion. I have shown that "return" cases are more often the result of lengthy detention than premature discharge. In our splendid new hospital the administration is well-nigh perfect, but we are no exception to the rule. What must be the case in towns where no warning is given of the danger run by being brought in contact with discharged patients and where, under a sense of security, these patients are allowed to mix freely with others? I leave your readers to judge. Their judgment will be assisted by a reference to the number of cases annually notified in the 32 large towns of England and Wales and London. Taking the latter city first we find that in 1891 there were 11,330 cases of scarlet fever notified in the registration county of London. The next year there were 27,093 cases and the year following 36,901. Liverpool in 1891 had 1176 notified cases. The next year she had 1554 and the following year 3538. Manchester commenced in 1891 with 1138 cases. In 1892 she had 1671 and in 1893 2031. Birmingham's figures run: 1892, 1418; 1893, 1614; 1894, 1788; 1895, 2964; and 1896, 3389. Leeds began in 1894 with 758 cases (eight months). In 1895 she had 874; in 1896, 1216; in 1897, 1791; and in 1898, 2002. Nottingham, which boasts the highest percentage of removals combined with lengthy experience of isolation, divides the honours with Bolton as providing the most complete object-lesson. Bolton, coming under notification so far back as 1879, and commencing her career without the advantages (?) of hospital accommodation, provides a useful example of how a town fares before and after. The figures are therefore given *in extenso* in these two instances.

Nottingham.

† Hospital opened.

It will be seen that the percentage of removals bears a more or less definite ratio to the number of cases so far as the former town is concerned, while in the latter (which was doing well without an aggregative institution) the opening of the hospital was signalised by an increase in the number of notified cases too gradual to leave us in doubt as to the cause. It is the fashion to speak of isolation hospitals as though they had existed from time immemorial, whereas many large towns have only had nine or ten years' experience of them and one—Leeds—only five, and in some of the large towns isolation is a dead letter to-day. These towns are at least as well off as Nottingham, Bradford, and other places where a high removal percentage has been the forerunner of endemic fever. I think it strange that when this system is attacked nobody attempts to defend it by the production of facts which tell in its favour. It is generally considered sufficient to meet the attack with a direct negative. It will occur to the unbiased reader that it is not enough to say that the system is a success, and he will feel with me that the importance of the subject demands that tangible proof shall be forthcoming that these institutions have in some remote corner of the earth done what is claimed for them Where are we to look for the evidences of prevention which these "preventable" institutions have brought about? If they exist surely it will not be difficult to point them out. That this has never yet been done is at least evidence *prima facie* that no such facts are obtainable.

You ask, Sirs, how I propose to deal with cases of plague and refer to the Great Plague of London. Dr. J. F. Payne in Allbutt's "System of Medicine" says that "under some circumstances the patient might be better isolated in his own home," but the question is too large to be dealt with here. It is surely not contended, however, that isolation hospitals—affairs of the last two decades—are responsible for the fact that the plague has not (till quite recently) visited these islands since 1665. If the ascertainable results of "isolating" cases of plague demonstrated that these precautions were instrumental in increasing the number and mortality of cases—as in the case of scarlet fever—I should not hesitate to denounce the system as a failure.

I am, Sirs, yours faithfully,
Dec. 10th, 1900. EDWARD DEAN MARRIOTT.

"THE WORKMEN'S COMPENSATION ACT, 1897: TWO VIEWS."

To the Editors of THE LANCET.

SIRS,—I gather from the editorial note at the head of the two articles under the above heading published in THE LANCET on Oct. 27th, p. 1227, that you, with your unique facilities of gauging medical opinion, consider that in the view of the medical profession grave miscarriages of justice do now occur, and must in future continually recur unless the fundamental safeguard of the Act is made compulsory—namely, that the medical referees called into being and initiated by the Home Office shall have their services called into requisition as was originally intended by the Act. In fact, the profession is agreed on the following points:—

1. That the non-employment of the medical referees appointed under the Act has been detrimental to the interests of both employers and workmen.
2. That medical referees would be more useful if they sat as medical assessors with the county court judges than if they only made a written report.
3. That the early reference to medical referees of cases in which no legal question is in dispute and in which there is a difference of opinion as to the amount of injury would save the time of the judges and much money to both employers and workmen.
4. That in the interests of the public generally the effects of accident should be differentiated from the effects of pre-existing disease.
5. That in every case the amount of injury should be assessed by an impartial medical man unconnected in any way with either employer or workman or with any society to which either belongs.

I shall be glad to hear your views authoritatively spoken as to the position of resident medical officers in hospitals, for at present house surgeons and other resident medical officers hold positions which could with difficulty be filled by others, they being on the spot and thoroughly conversant with the cases under their charge. I have never known hospital officials to be otherwise than absolutely impartial, and the opinions which they have given have to my knowledge saved an immense amount of litigation. Employers do not resist claims which they know to be *bonâ fide* and workmen cannot impose on employers when their injuries have been under observation by impartial medical men from the first.

I fully understand that it is impossible for you to insert individual opinions, but I feel sure that you are now in a position to judge rightly as to the questions raised and as they are of great interest to medical men and will be of still greater interest in the future I ask you to give, as you have so often done before, guidance which the profession as a whole may accept as authoritative.

I am, Sirs, yours faithfully,
ALBERT BENTHALL, F.R.C.P. Edin
Cockspur-street, S W., Nov. 24th, 1900.

ARSENIC IN BEER.

To the Editors of THE LANCET.

SIRS,—My attention has been called to the fact that in the "Notes on Recent Beer Poisoning in Salford," published in THE LANCET of Dec. 1st, I had in no way acknowledged the intimation stated to have been given me by Dr. Kelynack as to the presence of arsenic in inverted sugar. I was unaware until to-day that the verbal intimation had been left at my office, although I knew that Dr. Kelynack had called on me on Nov. 23rd, when he failed to see me, as I was absent pursuing the inquiries which resulted from Professor Delépine's discovery on the 22nd of the presence of arsenic in a sample of glucose. Although Dr. Kelynack's information reached me too late to be of use, I would have acknowledged the trouble he had taken to inform me what Mr. Kirkby had found had I been acquainted with the nature of the statement he had made to my clerk in my absence.

I am, Sirs, yours faithfully,
C H. TATTERSALL,
Salford, Dec. 7th, 1900. *Medical Officer of Health, Salford.*

To the Editors of THE LANCET.

SIRS,—There is no doubt that substances enter into the composition of modern beer which interfere with the usual methods of analysis for the detection of arsenic. This must have forcibly struck every chemist who has analysed beer for the presence of arsenic, as very many have, in beers brewed from arsenical glucose, and failed to detect it. Two of the nostrums used in the brewing of modern ales are finings, which are "cut" with sulphurous acid, and bi-sulphites of lime and magnesia, &c. These are both used as preservatives either in washing the barrels or by adding direct to the beer. If chemists had been acquainted with the presence of these in beer much less difficulty would have been felt in dealing with arsenical beer. Both these compounds will prevent the discovery of arsenic in beer by the Marsh test and by the Reinsch also, for unless the beer is boiled *some time* with acid *before* putting in the copper the sulphurous acid in the beer will produce the blackening.

Beers brewed from malt, hops, and glucose may be used direct in the Marsh apparatus, and if arsenic is present it will be detected. I have tried the experiment upon beer before racking when sulphurous acid had not been added. Thus it is not organic matter alone which makes arsenic in beer so difficult of detection, which I proved by taking a beer absolutely free and adding to it a known quantity of arsenious acid. In the Marsh apparatus I got out practically all I had introduced. To another portion of the same beer, with arsenic in such proportion as gave a large deposit in the heated tube, I added a very small quantity of a bi sulphite of calcium, and got no deposit of arsenic on the heated tube, only sulphur appearing there The arsenic was obtained from the flame at the end of the tube when received on porcelain The difficulty in connexion with the 12 samples of Manchester beer is now explained I had to do the samples in a day I did take 12 working hours and knowing nothing of the presence of sulphite I found no arsenic I may say that I had only about 11 ounces per sample, and in the small quantities which I used for experiments the trace of arsenic was probably lost in the preparation of the beer for the Marsh test I may premise that I tried a series of experiments with the original beer Any test to succeed must deal with not less than 100 cubic centimetres, and this should be charred *only to intumescence* with acid, then diluted and filtered, and the filtrate evaporated I did this process in flasks, but found that the medical officer here was doing the process in porcelain basins which I now adopt If one omits to evaporate the filtrate sulphurous acid may easily be present (carbonaceous matter and sulphuric acid) and spoil the experiment

I am, Sirs, yours faithfully,
CHARLES ESTCOURT,
Public Analyst to the City of Manchester
Manchester, Dec. 10th, 1900

To the Editors of THE LANCET

SIRS,—The obscure nature of chronic poisoning by small doses of arsenic has been shown in a startling manner by the wholesale beer poisoning outbreak in Manchester Does not the revelation point a moral as to the harm that may be done by administering small doses of arsenic in medicine over a prolonged period? That arsenic is an irritant to the kidneys, skin, mucous membranes, and all other excretory outlets to the body has long since been experimentally established Yet the drug is given daily by medical men and its use is extended over long periods of time In one case under the writer s care a patient had been treated with arsenic for years at various skin hospitals He is suffering from chronic Bright s disease, which in the absence of other assignable cause, may, not unreasonably be attributed to the arsenic It is a well known fact that during a course of arsenic a patient's urine may become albuminous So strongly have I felt upon this subject that personally I have practically ceased for years past from prescribing arsenic either in hospital or in private practice It has been said somewhere that arsenic never yet cured a skin disease—a dictum with which most dermatologists will be inclined to agree—although it undoubtedly now and then appears to modify favourably some cutaneous troubles The question arises, is it worth while for the sake of this remote possibility to expose a patient to the risk of grave mischief from the action of a virulent irritant poison upon excretory and other organs? Given in minute doses for a short time the drug certainly appears to exercise a beneficial effect in some cases of anæmia

In my own case arsenic has a curious effect I have on various occasions experimentally taken five minims of liquor arsenicalis and within 12 hours a fine punctate irritating rash appears on the back of the wrists I have little doubt that arsenic is answerable for some at least of the cases that present themselves at the skin hospitals Supposing a patient suffering from arsenical beer rash, so to speak, went to a hospital in Manchester there would have been no clue as to the nature of that eruption prior to the discovery of the poison at the breweries

I am Sirs yours faithfully
Bentinck street, W Dec 4th 1900 DAVID WALSH

PREVENTIVE INOCULATIONS AGAINST THE PLAGUE.

To the Editors of THE LANCET

SIRS,—A course of three lectures on bubonic plague was recently delivered in London at the Examination Hall of the Royal Colleges of Physicians and Surgeons by Professor Calmette, Director of the Pasteur Institute at Lille [1]

In the third of these lectures Professor Calmette described a new method of preparing a prophylactic against plague the product being a substance which possesses (in accordance with Professor Calmette's statements) the advantages that its strength can be easily determined and that it may be kept for a considerable time without becoming contaminated and without losing any of its immunising properties In this way he thinks that he has solved the problem of obtaining an easy and sure inoculation against the plague—a description which does not apply to Professor Haffkine's prophylactic

Professor Calmette's method consists in filtering off the plague microbes from their culture media drying them, and keeping the dried substance carefully in sealed bottles This substance can be easily weighed and dissolved in water, and it is then ready to be used for inoculation

In connexion with this subject I must advance the claim that a dried "vaccine' against the plague of definite strength and admitting of preservation was for the first time prepared by myself in collaboration with Dr Galeotti, as is shown by papers published in different periodicals in 897 and 1898 [2]

The method followed by us can be briefly described When plague microbes are cultivated on large agar agar plates they form a thin layer which is scraped off from the surface of the solid culture medium and treated with caustic potash By the strong alkali the microbes are not only killed but are also completely disintegrated and dissolved To the resulting solution, which is of a mucilaginous consistence, acetic acid is added till a white and flocculent precipitate is thrown down which changes on drying to a brown amorphous mass without losing its properties This precipitate is a nucleo proteid free from the metabolic products of the plague bacteria and when used for immunisation it is dissolved in a solution of carbonate of soda It is usually dried in vacuo and can afterwards be kept in sealed bottles and dissolved again in determinate proportions

The immunising properties of this "vaccine were fully demonstrated by numerous experiments made in the Pathological Laboratory at Florence and in the Parel Laboratory at Bombay at different times from 1897 to 1900 These experiments were performed on rats, rabbits guinea pigs, monkeys &c As regards the human subject, it was tried with good results in Florence in Bombay and in Australia, applications for it being made by the medical men of several towns of that country on the occurrence of the recent plague epidemics For the present it is prepared in the Vaccine Institute in Berne under Professor Tavel s direction

With this ' vaccine it is very easy to obtain a high degree of immunity in the human subject without any of those ill effects which follow inoculations made with other prophylactics—ill effects due to the impossibility of standardising the liquid and to the presence of other substances which are pathogenic without being in any way immunising By our method we isolate the only substance—the nucleo-proteid—by which immunity is produced and nothing but this substance is inoculated in proper doses, well dissolved in water and therefore in the best conditions for rapid absorption On the contrary, by Professor Calmette s method not only the active nucleo proteid but other substances composing the bodies of the bacilli are introduced into the organism and their solution and diffusion in the tissues are more difficult and slow

Therefore if Professor Calmette s claim of having obtained a better ' vaccine than Haffkine's is justified we can claim to have produced the best prophylactic of any since our "vaccine has not only the advantages shown by Professor Calmette s but also the other ones which have been mentioned above

I am Sirs, yours faithfully,
PROFESSOR A LUSTIG
Florence Nov 30th 1900

KIRKES' PHYSIOLOGY AND AMERICAN PIRACY.

To the Editors of THE LANCET

SIRS —Some months ago Mr John Murray publisher and proprietor of Kirkes' Physiology drew attention by letters to the press to the fact that an unauthorised edition of a book bearing the same name was being published and sold in America It may interest your readers, particularly those who have had to grapple with questions of international copyright, to know that this reprehensible proceeding still continues In fact a fresh edition of the unauthorised version has just appeared. In a recent number of the *Boston Medical and Surgical Journal* the following note is appended to reviews of the two rival editions:—

---

[1] THE LANCET, Nov 10th p 1366 Nov 17th p 1454 Nov 24th, p 1522.

[2] Deutsche Medicinische Wochenschrift, 1897, Nos. 15-19, Brit. Med. Jour, vol I, 1897 p 1027 and No. 2041, 1900

> It seems strange to the uninitiated on reading the above reviews to find two books, both called "Kirkes' Handbook of Physiology"; the reader will naturally stop and wonder which is the book. To explain this peculiar anomaly, by giving a short history of "Kirkes' Physiology," this note is written. About the year 1850 Dr. Kirkes, with the aid of the late Sir James Paget, produced in England "Kirkes' Handbook." This book, in vulgar parlance, "filled a long-felt want." It passed through many editions until at last Kirkes died; then, after passing through various minor changes, the editorship of the volume was assumed by Mr. Baker and Dr. Harris, and by them the book was kept up to date, Mr. Murray, the publisher, owning the book. In this country the book was reproduced by Lea Brothers and Co., and by them sold to Messrs. Wm. Wood and Co. (What they sold is a mystery, as they had no rights to sell.) This firm never had permission to use either the late Mr. Baker's or Dr. Harris's name in connexion with their publication. Still the publication and the sale went merrily on. Over four years ago Dr. Harris and Mr. Baker resigned their offices as editors. Mr. Baker is now dead and Professor Halliburton assumed sole control, producing the present English publication or Blakiston's American edition. Although Mr. Baker and Dr. Harris have had no connexion with the book for over four years Messrs. Wm. Wood and Co. still produce a "Kirkes" claimed to be edited by these men and revised for American consumption by Warren Coleman and Dr. Charles L. Dana. In Wood's edition under review several illustrations can be seen (those on blood crystals) which have been lifted bodily from Halliburton's edition and no acknowledgment made. There is also a remarkable similarity between the two editions in parts of the text. Perhaps this may be explained by the theory of telepathy. Of the two editions I understand that Blakiston's is the only edition published in this country with the owner's permission and from which the editor, Professor Halliburton, receives any remuneration. However, the present unfortunate state of international copyright law places no legal obstacles in the way of Messrs. Wood and Co.'s producing the book as they have done, but there is no doubt that fair-minded people will be shocked to find that in the noble profession of medicine men are found who assist in such questionable proceedings, even after personal protests not only from Mr. Murray, the owner, but also from Professor Halliburton. To sum up the whole matter, it simply means that Blakiston's is the authorised edition, while Wood's is not. *O tempora, O mores!!*

This statement is substantially correct. The figures of blood crystals which are specially mentioned as having been "lifted" were in the handbook before I assumed control. But other figures which have been added during my editorship have been pilfered. So that the ethics of the case remain unaltered. The editor of the *Boston Journal* is to be thanked for the determined stand he has made in the matter in the interests of international honesty.

I am, Sirs, yours faithfully,
W. D. HALLIBURTON.

King's College, London, Dec. 6th, 1900.

"SUGGESTIONS FOR THE PRACTICAL TREATMENT OF TYPHOID FEVER."

To the Editors of THE LANCET.

SIRS,—In Dr. W. Ewart's interesting paper on the treatment of typhoid fever published in THE LANCET of Dec. 8th he refers to the beneficial effects resulting from the administration of 20 minims of the liquor hydrargyri perchloridi with 15 or 20 minims of the tinctura ferri perchloridi every six hours—a plan recommended some years ago by Mr. W. B. Wedgwood of King's Lynn. Whilst fully endorsing Dr. Ewart's statements I nevertheless think it well to point out that the administration of the perchloride of iron should generally be restricted to those cases of typhoid fever in which diarrhœa is a prominent symptom. If there is a tendency to constipation other remedies may be used more advantageously.

Both the perchloride of mercury and the perchloride of iron act as germicides. That this is the case with mercury is well known. After being absorbed into the system it is afterwards largely eliminated by the mucous membrane of the intestines, both large and small, and so comes in direct contact with diseased surfaces. The perchloride of iron is also a germicide. It readily parts with some of its chlorine and so may be regarded more as a preparation of chlorine than of iron. To show that this is the case it is only necessary, as Professor Binz[1] has pointed out, to add a drop of the tincture or solution of perchloride of iron to a solution of potassium iodide mixed with a little mucilage of starch when a deep blue colour is produced, precisely as if pure chlorine water had been added. Tincture of guaiacum, the well-known test for nascent oxygen, also acquires a blue colour on the addition of a drop of the iron solution. The beneficial effect of the remedy is therefore, in my opinion, due chiefly to the chlorine which it readily gives up, and its action consequently must be exerted chiefly, if not entirely, on the contents of the stomach and duodenum. When there is a tendency to constipation I think that there is some risk the administration of iron of increasing both the tion and the pyrexia. In such cases a solution of euchlorine made from potassium chlorate and strong hydrochloric acid may be used as a drink from time to time instead of the perchloride of iron. The administration of euchlorine water, too, is also to be recommended in preference to iron for those individuals (and the number is not small) whose stomachs will not tolerate ordinary doses of the latter remedy.

Furthermore, the question arises whether calomel is not a better remedy in typhoid fever than corrosive sublimate. The former reaches the lower part of the small intestines before it is converted into the latter, and so acts more directly and specially upon the lower part of the ileum, where, as we know, the morbid changes are generally most marked.

In 1893 I discussed in THE LANCET[2] the action, not only of calomel in typhoid fever, but also of other remedies, such as the subnitrate of bismuth, tannic acid, oil of turpentine, &c., all belonging to the germicide class, and to that paper I would refer those who are interested in the subject. As I there pointed out, these are all old remedies—germicide remedies—their use, though empirical, suggested and adopted as a result of the keen clinical observation and experience of the physicians of a bygone age. The scientific investigations of the present day are only teaching us now how to employ these remedies with greater precision.

I am, Sirs, yours faithfully,
P. W. LATHAM,
Consulting Physician to Addenbrooke's Hospital, Cambridge.

Cambridge, Dec. 8th, 1900.

"THE TREATMENT OF SPRAINS AND OF SOME FRACTURES."

To the Editors of THE LANCET.

SIRS,—The address by Mr. Tubby on this subject is of much interest. As you have on two former occasions[1] been good enough to insert in THE LANCET communications by me relating to the treatment of recent sprains and dislocations by movement I would ask your permission to recur to the subject. After a pretty extensive experience of treatment by pressure by cotton-wool and bandage and also by strapping, especially at the time when Mr. Cotterill first published his book, which at present I am sorry I cannot lay hands on, I have a very decided preference for the movement treatment. Mr. Tubby says that there are two methods of treatment, one of which is by "rapid forcible movement immediately after a sprain." Then again, he says, referring to the treatment by mobility from the first: "It is one which can only be employed in very slight cases and even then with some misgiving, for in certain patients the symptoms instead of rapidly clearing away become more pronounced and permanent thickening and disability of the joint remain."

Is it necessary to use rapid forcible movement? My opinion is that forcible movement is generally employed (as a rule successfully) by the bone-setter after a patient has been under treatment by immobility for some time. A recently sprained joint is extremely painful and has at first to be handled very tenderly. Only very slight friction and squeezing can be borne. As the pressure is gradually increased the patient is encouraged to move his joint till flexion and extension are as complete as possible. No force is used. In the case of the ankle on attempting to walk the expression of surprise on the patient's face denotes that there is a considerable difference in the state of his joint. I am not speaking from the experience of a few cases, for I have employed movement in the treatment of recent sprains and dislocations for a good many years. I have used it for sprains of every degree of severity. Impairment of the usefulness of a joint may remain after a sprain, no matter what kind of treatment has been employed. I cannot remember any occasion in which I have regretted treating a sprained joint by movement instead of by any other method.

"SOME NOTES ON CASES OF MOVEABLE KIDNEY."

To the Editors of THE LANCET.

SIRS,—IN an article under the above heading by Dr. H. Davy, in THE LANCET of Dec 1st last, occurs the following statement: "Shortly after complete obstruction supervened and it was thought advisable, after consultation with Mr. A. J. Cumming, to perform lumbar colotomy. Mr. Harris performed colotomy in the ordinary way and he performed a most difficult operation extremely well, for he found the colon *completely empty*, and it is a matter of some difficulty to perform colotomy on an *empty* colon. Within a week the patient died," &c. The italics are mine. It would be of interest to hear what benefit was expected from this remarkable procedure. I am, Sirs, yours faithfully,

C. HAMILTON WHITEFORD.
Sussex-terrace, Plymouth, Dec. 8th, 1900.

"ARTHRITIS AND APPENDICITIS."

To the Editors of THE LANCET.

SIRS,—As a contribution to the discussion on the occurrence of arthritis in cases of appendicitis, reported in THE LANCET of Oct. 27th, p. 1203, may I recall the fact that French writers have often described arthritis as a complication of dysentery and in the discussion at the Medical Society of London Mr. F. C. Wallis referred to cases in connexion with ulceration of the bowel? This complication of dysentery appears to be very rare in India, but to judge by the amount of space devoted to it in French books on tropical diseases it must be more common in the dysentery of temperate climates In his recent book, "Maladies des Pays Chauds," M. Brault devoted no less than ten pages to the discussion of what he calls "le pseudo rhumatisme infectieux dysentérique," whereas the complication is not mentioned in Manson's "Tropical Diseases." It is certainly very rare, but I have recently met with one case in which on the third day the bowel symptoms suddenly ceased and well-marked arthritis of both knee-joints took their place.

I am, Sirs, yours faithfully,
W. J. BUCHANAN, M.B. Dub.,
Bhagalpur, Bengal, Nov 20th, 1900 Major I M.S.

THE USE OF COPPER FOR ELECTRODES.

To the Editors of THE LANCET.

SIRS,—I notice that in the last edition of Dr. Lewis Jones's work on "Medical" Electricity, as in most of the textbooks on the subject previously published, the electrodes to be employed in giving various kinds of electric baths are recommended to be made of copper. Now electrodes made of this metal rapidly discolour and corrode under the influence of the products of electrolytic decomposition of whatever fluid is used for the bath, and consequently are troublesome in use. I have been using for the last two years electrodes of thin sheet aluminium and find them practically untarnishable in the solutions usually employed and in every way much more suitable. In the case of aluminium the terminals should be clamped on, as soldering the metal is difficult and unsatisfactory. Possibly the hint may be of use to those of your readers who use electric baths in their practice.—I am, Sirs, yours faithfully,

RICHARD J. COWEN, L.R C.P. Irel., &c.
Clarges-street, Mayfair, W., Dec. 11th, 1900.

"OUR WIDOWS AND ORPHANS."

To the Editors of THE LANCET.

SIRS—I have read the letters of Mr. Heath and Dr. Cullingworth in THE LANCET of Nov. 17th (p 1459) and Dec. 1st (p 1610) respectively, pointing out the advantages of joining the Society for the Relief of Widows and Orphans of Medical Men.

May I ask, through the medium of your columns whether the scope of the society cannot be extended so as to include subscribers practising in any part of England? I do not know of any other society doing similar work, yet the benefits offered by the society are open only to those practitioners who join while they are living within the radius of 20 miles from Charing Cross.

There must be a large number of men who, like myself, never heard of the society when they were in London, and would now very gladly subscribe. Cannot something be done for us? I am Sirs, yours faithfully.

Dec. 3rd, 1900. A COUNTRY DOCTOR.

To the Editors of THE LANCET.

SIRS,—Thank you for your note *in re* medical charities, but let me have my growl. I have never been asked for a subscription until now for Epsom College and have often wondered how the institution was financed. As to the British Medical Benevolent Fund, I never heard of it before. How many practitioners are similarly placed? Why not present to every man an appeal when he receives his certicate of registration?

I am, Sirs, yours faithfully,
Dec. 8th, 1900 A.K.C. LOND.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Great Rise in Plague Mortality.—The Famine.—Decoration of Bombay Plague Nurses.

I HAVE to record for the week ending Nov. 18th a great rise in the mortality from plague throughout India, largely due to the recrudescence of the epidemic in Bengal. The deaths were 2963, a rise of 776 on the previous seven days. In Bengal the deaths were 583, a rise of 242 The death-roll is increasing in all the affected districts which are Gaya, Saran, Patna, and Monghyr. For the corresponding week of last year the deaths from plague throughout India were 2968, so that the general condition of things can hardly be said to have improved. The Mysore State is still suffering heavily and records 932 deaths, as against the previous return of 831. There is a decided decrease in the Bombay Presidency as well as in Bombay city Information has just been published from Lahore of an outbreak of a very virulent type of plague at Darnam in Gurdaspur district. It is said that the death-rate in Hissar is appalling and the people are all seriously debilitated from the prolonged famine. Plague is rapidly going down in Poona. Both the cities of Calcutta and Bombay continue to return very high death-rates. For the past weeks of November the rate in Calcutta has been about 45 per 1000 per annum—the average being only 35 For the same period in Bombay it has been about 47 5 per 1000. In both cases also there is no satisfactory explanation given of the increases. In Calcutta cholera and small-pox are only about the average, but there is an increase under fevers and bowel complaints and especially under "all other diseases." Plague deaths are now merely nominal. In Bombay much of the increase seems to be recorded under phthisis and diseases of the respiratory organs. Large numbers of people from the famine districts have immigrated to Bombay and it has been found necessary to convert the old Grant-road Plague Hospital into a sort of workhouse infirmary where Mrs. Adams Wylie is distinguishing herself in nursing and charitable work.

The numbers under famine relief will soon cease to be published, as the decrease during the past week has been nearly 250 000 and at the present time the total under relief is only 554,787. The Bombay Presidency and the Central Provinces continue to be the chief districts afflicted, but the Baroda State and some of the Bombay native states still record large numbers.

Even after a considerable lapse of time it is pleasing to note the recognition of services of some of the plague nurses during the earlier periods of the epidemic A presentation lately took place in Bombay by Lady Northcote to three nurses who have especially distinguished themselves in connexion with plague work in the city. Nurse Leavers, Nurse Remy, and Sister Mary Edith have been made Honorary Nursing Sisters of the Order of St. John of Jerusalem and the presentation of the badges and diplomas were formally made to them. It must not be forgotten that there are at least a dozen others who have worked equally well and arduously. Many of these were mentioned by name at the public meeting, but honours and decorations can only fall to a few.

Nov. 22nd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University of Birmingham.

THE Principal of the University, Dr. Oliver Lodge, delivered an address to the students on Nov. 28th on the Aims and Hopes before them in the new University. There was a crowded audience, the chair being taken by the Vice-Chancellor, Alderman Beale. This was the first public occasion on which the University assembled as such, and much interest was exhibited in the proceedings. Defining the term "university," the Principal spoke of it not as a building, but as a society—an assemblage of students combined together for mutual help and coöperation. "Unity of aim and diversity of method" was the keynote of valuable and forcibly expressed statements as to "the production of strong and useful citizens to go out to the furthest limits of the great English-speaking commonwealth" in different capacities and there to serve their kindred and their race in a hundred different ways. A students' council was suggested and the social and recreative side of the student's career was emphasised. Many important suggestions were made in the course of the address which was illustrated by appropriate similes and humorous allusions. High ideals and lofty aims were set before the students as part of the thoroughness which ought to characterise their efforts. In language gracefully expressed, yet in dignified terms, the Principal sketched the aspirations of a great university and foretold the vast influence for good such an institution would bring to bear upon the community at large. The address was listened to with much interest and unanimous opinions were expressed as to its excellence and power. Already the effect of some suggestions made has been witnessed to by the appointment of student representatives on the council of the University.

Some Criticisms.

But already some rifts have appeared in the lute, though of somewhat unimportant character. The University has had a seal made which is intended to embody certain traditions in its symbolic features. Among others the derivation of the name of the city of Birmingham is represented by sprays of "broom" around the margin of the seal. This, competent critics declare, is entirely an error and that the word "Bromwicham" or "Bromicham" dates from the seventeenth century only, whereas the town existed long before. If this derivation was really the true one there would be some justification for the appellation of "Brummagem." History shows that we are influenced much by phrases, and if the unreal enters as an element into these heraldic bearings some obloquy may be associated with the place itself. Again, complaints have been made that the fees of the University as charged to students are too high. There is no ground whatever for this allegation. They are calculated at about the same rate as—or even lower if anything than—the English university colleges and are not intended to compare with Scotch universities where the Government grants and conditions are entirely different.

The Consultative Medical and Surgical Institution.

In consideration of the finding of the General Medical Council the authorities of this institution have agreed to withdraw and as far as possible to recall all advertisements relating to the medical aspect of its constitution. This resolve was the subject of a communication to the Council during the recent sitting, but that body wisely determined not to entertain it as their judgment is not to be pronounced until next May. In the meantime much controversy and some bitterness are being shown concerning the methods of those who promote the cause. The epithet of "street doctor" applied by the leading spirit of the movement is an uncalled-for and unnecessary term, which has provoked much rancour and recrimination. The institution may fairly be allowed to stand or fall upon its own merits. The opinion of the profession being expressed in clear and unmistakable terms it is confidently expected that the misjudged "philanthropy" which started it will meet with its decline and fall in due time.

The Dental Hospital.

The forty-first annual meeting of the subscribers and friends of the Dental Hospital was held on Dec. 7th. The report showed a balance of £493, of which £450 would be reserved for building at the expiration of the lease. The mechanical department showed that the supplying of artificial teeth would prove one of the most important parts of the future work. The necessity of building a new hospital was conclusively demonstrated. In 1900 there were 27,273 cases, including 15,669 extractions, while the value of the work had increased tenfold. It was estimated that a new building would cost £10,000, while £5000 would be required to fit it up Some allusion was made to the influence of the new water-supply upon the teeth. Various votes of thanks were then passed.

Birmingham Musical Festival.

On Dec. 7th the Board of Management of the General Hospital received a cheque for £6009 6*s.* 7*d.* from the Orchestral Committee of the late Musical Festival, being the profits from this year's performances. On three previous occasions only has this amount been exceeded—namely, in 1870, 1873, and 1876.

Dec. 11th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Chemists and Arsenical Beer.

AT the meeting of the Manchester Section of the Society of Chemical Industry on Dec. 7th some conversation took place on the subject of beer-poisoning. The chairman (Mr. H. Grimshaw) said that though they had heard so much on the subject there was little that was definite. Mr. J. Carter Bell had found that many of the processes for detecting arsenic which he had tried did not work satisfactorily. He had not come across any sample of beer "loaded," as had been said, with arsenic, but he had returned the quantity found in a bad sample as "0·2 of a grain calculated as arsenious acid in one gallon of beer," so that 100 gallons of beer would contain about two grains of arsenic. He added that the Marsh test had not proved trustworthy in showing minute traces of arsenic in beer, which as ancient history was interesting. Mr. Duncan stated that he had often had to test for arsenic and he had found in beer one-tenth of a grain to the pint. This was outside Manchester and before anything had appeared in the papers. He was asked to look for lead, antimony, and tin, which he did not find, but tested for arsenic, which he did find. Dr. Gerland spoke of the difficulty in using the Marsh test caused by the presence of organic matter. Mr. F. Scudder considered that in testing for arsenic in beer at least a litre should be used. He thought that it was important to ascertain the toxic effect of arsenic when combined with alcohol. "It was" said to be "in some cases customary for a man to drink two gallons of beer, and it might be that while 0·04 of a grain of arsenic would not of itself produce ill-effects it might when combined with alcohol have a particular therapeutic effect." As was to be anticipated, the epidemic of arsenical poisoning—or to put it differently, of peripheral neuritis associated with the drinking of beer—has been widespread, but as the authorities are on the *qui vive* and the public have been abundantly warned it may now gradually subside. There seems to be a general hope that this lamentable visitation may lead to the use of malt and hops again, free from the intrusion of "substitutes."

The Manchester Corporation and Beer-poisoning.

It was officially announced yesterday by the Sanitary Committee of the Manchester Corporation that the brewers and retailers of certain beer in samples of which the city analyst has found arsenious acid are to be prosecuted. Dr. J. Niven, the medical officer of health of Manchester, has written to the honorary secretary of the Confectioners' Association stating that in three samples of glucose, two used in making cheap sweets and one used in making jams, no trace of arsenic was found.

Manchester Volunteer Medical Staff Corps.

A further appeal for funds is being made by the Volunteer Medical Staff Corps of Manchester to enable them to provide suitable headquarters and drill accommodation. A first subscription list is being prepared which is headed by Honorary Surgeon-Colonel Walter Whitehead with £100 The sum required will not be less than £12,000. Each company consists of four officers, three of whom must be qualified surgeons, and 100 men. The latter are drawn from all classes. The artisan, the clerk, the labourer, the warehouseman, the railway porter, the student, may all be found in the ranks. They are trained in drill, nursing, physical exercises, "first aid," and in the safe and easy transport of the sick and wounded on stretchers, on hand seats, in wagons, cacolets, railway trains, &c.; further, as the men have to drive the ambulance wagons, some are trained in riding and driving and in the care and management of horses. Almost nightly work is done in Manchester and the corps goes for training every year alternately to Aldershot and to the hospital at Netley. The strength of the corps equals that of the London corps, which speaks much for the zeal and activity of Manchester and the district, but it suffers from want of adequate and proper quarters. This body of men is fitted for useful work in peace or war, for in cases of accident their training must make them the most skilful and best disciplined helpers, and in case of threatened or actual invasion they would be prepared to do their duty to the full, as witness the work done by volunteers from the corps in South Africa. Even if the wave of self-sacrificing patriotism is less evident than when it first arose, the £12,000 asked for will be well spent if considered as part of the insurance premium which our country must pay for the blessings of peace. Manchester will not act up to its reputation if this appeal does not meet with a generous response.

The Ancoats Hospital.

At the annual meeting of the friends and supporters of the above hospital it was stated that an offer of £10,000 had recently been made by an anonymous donor to the hospital for the purpose of providing a convalescent home. The committee hope soon to be able to provide a comfortable home for 12 men and 12 women. A site has not yet been secured, and Mr. E. S. Heywood, chairman of the Manchester Royal Infirmary Board, advised the committee not to be in too great a hurry in deciding on a site, and "to select for the convalescent home a place where there was a little life, and, consequently, something going on that would prevent the patients from feeling dull." This advice is no doubt sound, for among the class from which the patients come there are few who would not soon feel bored by the peaceful quiet of even the most beautiful park-like scenery if it were unenlivened by human interest.

Charitable Bequests.

Under the will of the late Mr. F. Rothwell, a Manchester brewer, a sum of £24,000 has already been distributed to various public institutions and a further sum of £14,999 has been paid into the Chancery Court of Lancashire to be distributed according to a scheme approved by the court, and of this about half goes to Manchester and Salford charities, the various medical charities benefiting to the amount of £3200.

Dec. 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Society of Edinburgh.

AT the monthly meeting of the Royal Society of Edinburgh, held on Dec. 3rd, Dr. Richard J. A. Berry, Edinburgh, read a paper on the True Cæcal Apex, or the Vermiform Appendix, its Minute and Comparative Anatomy. The lecture was illustrated by lantern slides. Little had hitherto been done, the lecturer said, in the investigation of the comparative anatomy of the vermiform appendix. In his own investigations on this subject he had used three types of animals—the rabbit, the cat, and the pigeon. He found that in the majority of animals examined the lymphoid tissue in the cæcum was largely in excess of that contained in other parts of the large intestine. The line of demarcation between the two was in many instances, such as the pigeon, the rabbit, the cat, the mouse, the rat, the dog, and the striped hyæna, most sharply marked. The cæcum was thus in warm-blooded animals and the higher vertebrates a special seat of lymphoid tissue. Furthermore, the vermiform appendix in man represented the true apex of the cæcum. It was further proved beyond all doubt that the characteristic feature of the normal human appendix was lymphoid tissue. All those facts led to the conclusion that the homologue of the vermiform appendix in animals was the cæcum. He had shown in his work on the subject that in animals the seat of the lymphoid tissue in the cæcum varied considerably. In the pigeon it occupied the entire cæcal wall, in the mouse and rat the lateral wall of the cæcum near its apex, while in most animals it was found to be collected at the apex of the cæcum. Assuming the view to be correct that the lymphoid tissue tended to be collected into a specially differentiated portion of the cæcum, it might be expected from a knowledge of the laws of evolution that occasionally an appendix would be found in some of the lower animals. This was actually the case in two of the lower animals, the wombat and the capybara His conclusions were: (1) that lymphoid tissue was the characteristic feature of the cæcal apex (the vermiform appendix of man was therefore represented in the vertebrate kingdom by a mass of lymphoid tissue situated usually at the cæcal apex); (2) that as the vertebrate scale ascended this lymphoid tissue tended to be collected together into a specially differentiated part of the intestinal canal—the vermiform appendix; and (3) that the vermiform appendix was therefore not a vestigial structure, but a specialised part of the alimentary canal.

Professor Chiene on his South African Experiences.

On Saturday, Dec. 1st, Professor John Chiene delivered a lecture to the members of the Edinburgh University Union on the views and impressions which he had formed during his stay in South Africa. He gave an outline of his journeys in Cape Colony, Natal, the Orange River Colony, and the Transvaal, and then described the various hospitals which he visited as consulting surgeon He had been able to do a good deal for the wounded at Mafeking, having arrived there just two days after the relief of the town. He described the Edinburgh Hospital at Norval's Pont. He hoped it would long remain a hospital at this or some other important point on a main line of railway, and that many of our soldiers would get much benefit in time to come within its walls. Everywhere he went he met old students of Edinburgh University, from whom he had received the greatest kindness. It was an interesting fact that three of the hospital trains at the front were in charge of Edinburgh men. In the course of his journeys he had met Dr Pretorius, with whom he had a conversation. He had never come in contact with any British soldier who had been under the charge of the Boer doctors who had not expressed to him gratitude for the kindness they had received at their hands. Professor Chiene spoke highly of the various hospital trains. On his way home he visited St. Helena and met there some of his Boer friends whom he had seen at Mafeking. He had been glad to help them at Mafeking and they were equally glad to see him at St. Helena, where he found them looking well and as if well fed. He had there become acquainted with Cronje and his wife. Cronje had spoken to him of all the kindness he had received at the hands of the British.

The Health of Edinburgh.

The report of Sir Henry Littlejohn on the health of Edinburgh in October was submitted to the Public Health Committee of the town council on Nov. 27th. The report showed that on that date there were 320 patients in the City Hospital for Infectious Diseases. Of these 43 were cases of diphtheria, 25 of typhoid fever, 147 of scarlet fever, and 81 of measles. These figures show that there is a large increase in the number of cases of diphtheria, there being usually only 14 or 15 cases of that disease in the City Hospital. There did not appear to be any definite source of infection.

Glasgow University Club, London.

The members of this club dined together on the evening of Dec. 5th, at the Café Royal, Professor Sir Hector C. Cameron, M.D., being in the chair. There was a large attendance, and among others the chairman has supported by Lord Lister, Sir J. W. Batty Tuke, M.P., Sir W. T. Gairdner, K.C.B., Surgeon-General Jameson, C.B. (Director-General of the Army Medical Service), Major Babtie, V.C., C.M.G., and Dr. W. Bruce. The toast of "The Queen" having been duly honoured, the chairman proposed "The Club" and in so doing referred to the extensive scheme for the provision and extension of laboratory accommodation upon which the University authorities in Glasgow are at present engaged. The financial aspect of this scheme was necessarily a somewhat anxious one, but it could not be doubted that the money required would be forthcoming. In 1901 the University would celebrate its ninth jubilee, and the occasion was to be marked by an elaborate series of academic ceremonies, and he hoped also by substantial additions to the University resources. The next toast, submitted by Surgeon-General Jameson, was "The Health of Major Babtie, V.C., C M G.," who is a graduate of Glasgow University and who gained the Victoria Cross at the battle of Colenso for his heroism in going forward under a heavy fire to attend to the wounded and to succour the late Lieutenant Roberts, V.C. Sir William Gairdner spoke a few words in support of the toast, which was drunk with Highland honours. It was announced that Major Babtie had been elected an honorary member of the club. The other toasts included "The Guests," proposed by Mr. James Campbell, M P., to which Sir J. Batty Tuke replied, and "The Chairman," proposed by Lord Lister, who made some interesting references to his association with Sir Hector Cameron in the Glasgow Royal Infirmary where the early developments of the antiseptic system first took practical form. The dinner was marked by much enthusiasm and was, in every sense, a conspicuous success.

An Important "Skim Milk" Case at Glasgow.

Decison has just been given in an important test case, in which, under the Food and Drugs Act, at the instance of the corporation, a dairyman was charged with having sold as "skim milk" milk which was deficient in fat or cream to the extent of 0·72 per cent. Evidence had been given by experts from Glasgow, Edinburgh, and London, and by many prominent farmers, dairymen, and sanitary officials. The milk in the case in question had not been skimmed by hand but had been "separated" by mechanical means till only 0·28 per cent. of fat remained in it, and the question came to be simply whether such milk could properly be sold under the name "skim milk" or whether it ought not to be labeled distinctively as "separated milk." It was not a question of adulteration, but of the extent to which fat may be removed from milk. The prosecution drew the line arbitrarily at 1 per cent. of fat and held that unless at least this percentage is left the milk is not of the "nature, substance, and quality" of the article demanded by a purchaser who asks for skim milk. The respondent refused to accept this 1 per cent. standard, or any other standard, and boldly claimed the right to remove the entire fat if he could and still to sell it as skim milk. It was common ground among the witnesses that milk is still milk though all its fat be removed, so that its nature is not changed; it was also commonly admitted that, apart from its fat, milk contains other valuable food constituents which are not affected by the mechanical removal of the fat The sheriff put aside the argument as to danger to infant life from the use of such milk, as even the 1 per cent standard insisted on by the prosecution fell very far short of the proportion of fat requisite for a child fed on milk alone Further, the Acts did not profess to regulate diet or to prescribe the proper food for infants and did not condemn any article which was good for food merely because if wrongly used it might be injurious to health. The Acts only held a retailer to be in default if he sold an article which was not what he represented it to be. It was held now that the machine skimmer did not alter the nature, substance, or quality of the milk and was therefore not struck at by the Acts, and this view was strengthened by the fact that the machine did not necessarily remove the fat to a greater extent than did hand skimming, or it might be regulated so as to remove a greater or smaller proportion. The amount removed by hand depended on the length of time during which the milk had stood and the deftness of the skimmer, and even hand-skimmed milk might contain less than 1 per cent. of fat. Somerset House authorities had therefore so far refrained from drawing a hard-and-fast line. Sheriff Fyfe went further, being evidently inclined to the view that the increased degree to which the fat was removed was compensated for by the freshness and cleanliness of the machine-skimmed milk. Such milk was not usually allowed to stand for varying lengths of time in shallow dishes, but was at once treated and the centrifugal force employed seemed to be calculated to separate all possible impurities (bacterial and others) from both milk and cream. [The sheriff might also have stated that milk is usually sterilised before being treated in the separator.] In the absence of a standard of fat for "skim milk" the decision went against the prosecution—"the article of
commerce known as skim
description whether the fat in
cent., or nothing." The learned
less right enough as an interpreta
subject, but it makes clear the
distinctive labels, as "milk,"
"separated milk," and the fo
standard for each. Milk from wh
removed is properly a fluid prepare
is not.

of the counties of Armagh and Down. He grad
Royal University in 1884 and is a Licentiate o
College of Physicians and the Royal College of
Edinburgh.

The Nursing Question in Armagh Union.

At the weekly meeting of the Armagh Guar
Nov. 27th an important discussion took place on th
question. Some months ago the guardians sel
assistant in the infirmary a probationer nurse, an
ment which the Local Government Board refused to s
and three months afterwards the guardians were fo
dismiss her as the Local Government Board refu
sanction the appointment. The same central author
Dublin wrote to the master and medical officer statin
they would hold them responsible for the proper nursi
the sick in the infirmary and referring them to the n
order of September, 1897, where, acting under the requis
of the medical officer, the master was bound to appoi
qualified nurse until the next meeting of the board.
medical officer of the infirmary having requisitioned
master he procured the services of a trained nurse
assistant in the infirmary, and the matter coming before
board of guardians at their next meeting they una
mously refused to sanction the appointment or to ha
anything to say to it, and by their direction the
solicitor was told to take the advice of The MacDermot
Q.C., on the following questions. Whether the Loca
Government Board were acting within their powers when
they authorised one officer of the union, the master, to
employ another officer, the temporary nurse. If counsel
was of opinion that the Local Government Board were
acting within their powers, in so doing, the guardians
desired to be advised whether the master was authorised to
continue the services of the nurse from week to week con-
trary to the wishes of the guardians, expressed in their
resolution; whether the guardians were liable to pay all or
any part of the remuneration due for the services of the
assistant nurse appointed; and whether, under all the circum-
stances of the case, the guardians were compelled to appoint
a permanent assistant trained nurse, or whether the guardians
had complied with all lawful requirements when they
appointed a probationer nurse, which appointment the Local
Government Board refused to sanction. The MacDermott
advises the guardians to contest the case and gives his opinion
that the guardians were correct in their action. He recom-
mends that a notice be served on the assistant
affirming her being, or having been, one of

informing her that no payment will be made to her by the guardians, a communication to the same effect being made in respectful terms to the Local Government Board The MacDermott says that the mode in which the question can be raised is by refusing payment, just as in the case of the temporary medical substitute recently decided by the Queen's Bench in Ireland adversely to the Local Government Board It was unanimously decided by the guardians that their solicitor should be instructed to carry out all the recommendations of The MacDermott, Q C The next move must be made by the Local Government Board The guardians are determined to fight

The Belfast Medical Students Association

The inaugural meeting of the Medical Students' Association of Belfast was held on Nov 30th, in the McMordie Hall of the Students' Union There was a large attendance The President, Mr Walter Phillips, B A, medical student, delivered an address in which he traced in a very literary way the relationship of magic, alchemy and astrology to medicine Afterwards Dr J A Craig, demonstrator of anatomy, read a paper on Some Impressions of the Vienna Medical School in which he gave an account of a visit to the school The President of Queen's College, Dr H O Neill Professor T Sinclair, Professor R O Cunningham, and Professor J A Lindsay subsequently addressed the meeting

The Bacterial Purification of the Drainage of Belfast

The corporation of Belfast have very wisely decided to obtain further advice as to the proposed scheme of purifying the Belfast drainage by bacteria beds, and they have appointed Professor G A Letts, D Sc professor of chemistry, Queen's College, Belfast, and Dr J Lorrain Smith lecturer on pathology in Queen's College Belfast as experts to examine and report at as early a date as practicable, on the scheme for purifying the main drainage and on its effect on the Belfast Lough They are to be paid 150 guineas each This course of action is the one which was recommended in THE LANCET of Sept 22nd, 1900, p 909

Health of Belfast

From the report presented to the city council at their monthly meeting on Dec 1st it appears that between Oct 21st and Nov 17th 1900 there were 334 cases of zymotic disease notified the largest number being 127 cases of typhoid fever 48 deaths from zymotic disease occurred The annual death rate from all causes was 18 5 per 1000, which is lower than is usual at this season of the year Scarlet fever of a mild type seems to be prevalent In the discussion which followed the presentation of the report some scepticism was expressed as to the working of the Notification of Diseases Act, it being stated that medical men in better class practices evaded the law in not reporting cases and that the same case was reported by several medical men I doubt these charges, but if they are true it only shows what inadequate measures are taken by the public health officials to see that the law is properly carried out

Extraordinary Rainfall in November

November has been in Ulster a very wet month, the rainfall reaching 6 06 inches, being 1 65 inches more than in the corresponding month of last year 1 50 inches more rain have fallen in the 11 months of this year than fell in the corresponding period of 1899, this being due almost entirely to the excess of the amount in last month Only 11 days in November passed without rain, and in one—Nov 24th—the amount of rain as measured was actually 1 40 inches.

Dec. 1 th.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Drinking water Question

THE "water lords" have at length been moved by the protestations of the public and the press against the half rations system of the supply of spring water at certain times in the year Their works committee has brought forward a plan which will cost 300,000 000 francs, but which will for a long time at least do away with any fear of a water famine The first part of the scheme consists in as soon as possible utilising certain head waters of the Ayre which belong to the city and are at present used for nothing The existing main which carries water from the Avre is of quite sufficient diameter to carry the additional supply The second part of the scheme consists in making use of water from the Val d Orléans, which practically means the taking up of the sources of the Loiret for it is intended to make use of the subterranean springs in that district The city of Orleans, however, and all the towns which are carrying on a campaign in favour of making the Loire navigable, are up in arms against this proposal, but the engineers hope to overcome opposition by the promise that the water taken shall be given back by means of storage basins They hoped, too, that the Soissons greensand would be found to yield water enough to assist very considerably in supplying Paris, but the results of borings have not come up to expectation Before undertaking these expensive works which will necessitate as before mentioned, an expenditure of 300 000,000 francs, it would be as well to notice exactly what are the present conditions existing in the city of Paris and to consider whether this new and costly source of supply is necessary or whether that supply which the Parisians already have could not be better distributed, due precautions being taken to avoid contamination The estimated consumption in Paris averages 230 litres per head per diem but in times of drought this amount is very possibly reduced to 150 litres, which is all the same quite sufficient The scarcity of water is in great part due to the shameful waste of water which occurs in the cooling of "drinks" It takes about 200 litres of water to cool two bottles of water and one bottle of wine There must also be taken into consideration the idiotic custom of the authorities in making use of spring water for flushing water closets and working lifts The best remedy would be to supply houses with river water for such purposes but for this end pumps would have to be erected which would supply the water at sufficient pressure and the requisite piping would cost about 80,000 000 francs The next remedy would be that every water consumer should use a meter He would thus only pay for what he consumed and waste would be avoided, and he would no longer cool his wine with water which he would find to cost about six times as much as the ice necessary for the same end The establishment of meters would cost the city about 40 000 000 francs, and therefore the carrying out of these two schemes would only cost 120 000 000 francs as against the 300 000 000 francs which the taking up of new gathering grounds would cost In any case the watching committee of the Paris drinking water supply, after considering the report of M Duclaux, Director of the Pasteur Institute came to the conclusion that certain measures should be taken to avoid contamination of the sources of supply already in use These measures are as follows 1 Careful examination of the borings at the springs save in the case of those of the Loing where they have been carried out in the most modern style and with every precaution 2 A protection zone for the gathering ground which shall be in some cases at least 100 square kilometres in area Special medical surveillance is to be exercised within this area and in case of the notification of a case of typhoid fever within this area special measures of disinfection shall be taken as regards every sick person 3 General prophylactic measures such as disinfection of communal gutters and gullies situated within the protected zone and care to be taken that infected waters do not by earth filtration mingle with the springs These rules are of course to apply to any new source of supply which may be hereafter taken up as well as to those at present in use The committee has in hand the question of the admixture of water from different springs and that of the admixture of spring with filtered river water

Obituary.

The death is announced at the age of 83 years of Dr Jules Etienne Bergeron permanent secretary of the Academy of Medicine and Vice President of the Consulting Committee of Hygiene Dr Bergeron was born at Moret in the Department of Seine et Marne in 1817 In 1852 he was nominated, after public competition, as physician to the hospitals and commenced his career at the Rochefoucauld Hospital He also served at the St Antoine and the Trousseau Hospital Dr Bergeron made a great name for himself in the treatment of children and in 1865 he became a member of the Academy of Medicine He had held the post of Vice President of the Consulting Committee of Hygiene since 1884 and had been permanent secretary of the Academy since 1887 Dr Bergeron has left a number of works dealing with rabies, with tinea and with the diseases of children, and a very elaborate treatise upon the Repression of Alcoholism, which last was published in 1872. He was *Officier* of the Legion of Honour.

Dec. 11th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch on Malaria.

AFTER a long absence Professor Koch has now returned home, his investigations of malaria being for the present terminated. Following his practice in the case of his first reports which have been already referred to in these columns[1] he has published a final account in the *Deutsche Medicinische Wochenschrift*. His last researches were carried out in the Caroline and Marianne islands where he stopped while proceeding homewards by way of New Guinea and Hong-Kong. As I have already mentioned, Professor Koch insists on the necessity of examining the blood of children in places where the adult population is free from malaria, this being the only way of obtaining reliable results. He, therefore, in Ponape and Saipan examined 79 and 24 children respectively, the result being that neither enlargements of the spleen nor parasites in the blood were detected. Both islands were in fact free from malaria. In both islands he found a great many cases of frambœsia, a disease also termed "yaws" by English medical men. This disease being very little known and therefore often confounded with syphilis Professor Koch suggests that the Colonial Department should send a specialist for diseases of the skin to these islands. From Hong-Kong Professor Koch proceeded to Egypt to make himself acquainted with the contradictory opinions regarding malaria held in that country. He found several cases of malaria in Alexandria and foci of endemic malaria at Heluan, near Cairo, and at Wadi Natrun, situated in the desert in the west of the Nile Delta. In order to include the facts relating to malaria in Germany Professor Koch requested Professor Frosch of the Institution for Tropical Diseases to examine some of the places where the disease had formerly been endemic—as, for instance, on the coast of the North Sea in Schleswig-Holstein. According to the report of this gentleman the disease is rapidly decreasing in Germany, and only a few isolated cases, but no focus, could be detected.

Bactericidal Action of the Ultra-violet Rays of the Spectrum.

In a preliminary communication to the *Deutsche Medicinische Wochenschrift* Dr. Strebel of Munich announces that he has succeeded in ascertaining that certain invisible rays produced by a powerful induction coil are able to kill bacteria. Micrococcus prodigiosus, for instance, is destroyed by these rays in 20 minutes even when thick screens of quartz are interposed. The spark of the induction coil is in any case rich in ultra-violet rays, and by using certain substances as electrodes and a Leyden jar as regulator and accumulator of the electricity the amount of ultra-violet light is considerably increased. Dr. Strebel used aluminium and cadmium as electrodes; in this way he increased the invisible ultra-violet portion of the spectrum so much that it became four times longer than the visible part. The ultra-violet light was made visible by projection on a screen of barium platino-cyanide. Dr. Strebel has found that in the apparatus of Professor Finsen of Copenhagen for the treatment of lupus the ultra-violet rays are almost totally absorbed, so that its bactericidal power depends on the relatively feeble action of the visible blue and violet rays. By this new discovery a powerful bactericidal effect is obtained from light, and the method is made so simple that any form of Roentgen ray apparatus may be employed therapeutically as a source of light instead of the complicated and expensive apparatus of Professor Finsen. Dr. Strebel is now occupied in determining the permeability of certain media by the ultra-violet rays and their action on the different species of bacteria. He is also trying to ascertain whether the rays given off by uranium and radium, of which the action is similar to the x rays, are bactericidal and therefore capable of being used in the treatment of diseases of the skin. A more detailed account will be given by Dr. Strebel in a few weeks.

Some Reforms in the Army Medical Corps.

The Army Medical Department has decided to complete the organisation of the Kaiser-Wilhelm-Akademie, the training school for army medical officers, by the appointment of a "scientific council." According to the *Vossische Zeitung* the council will consist of 15 members under the presidency of the general staff surgeon of the army and its duty will be to advise the Army Medical Department in scientific questions of every kind. The council will deal with questions relating to the curriculum of the students of the academy, the organisation of its collections and laboratories, and the post-graduate study of military surgeons. In addition to questions connected with the academy the council will be consulted in matters of military hygiene, especially the prophylaxis of epidemic diseases, and in difficult judicial cases the council will give a professional opinion when a court-martial requires advice as to the state of mind of an accused person. The names of the members of the proposed council are not yet known, but probably they will consist not only of army medical officers, but also of prominent civilian medical men, hygienists, &c. As the general expenses will be 3000 marks (£150) per annum membership of the council will be an honorary position only. Another reform will be the abolition of the examination for the rank of Oberstabsarzt. This examination was on matters of special military interest only and had to be passed before a special commission in Berlin consisting of military surgeons and Professor Koch, Professor Bergmann, and Professor König of Berlin University. Those who wished to be promoted to the higher ranks in the active as well as in the reserve Army Medical Corps had to present themselves. The reason given by the War Office for the abolition of this examination is that the professional training of army medical officers has at present become so good that a special examination is no longer necessary. The duration of post-graduate courses will be extended from three to four weeks every year, and a greater number of military surgeons will have the opportunity of taking part in them. By these measures the War Office expects to induce civilian medical men in greater number than before to enter the active Army Medical Corps, the members of which have hitherto almost exclusively come from the Army Medical Academy.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Discovery of a Statue of Æsculapius in the Roman Forum.

AMONG the recent interesting finds in the Roman Forum is a statue of Æsculapius. It was lying face downwards under the central niche of the large arched space surrounding the Well of Juturna, which has lately been excavated under the direction of Professor Boni. The head of the figure and the middle of the right arm are wanting, but the other parts are well preserved. It represents the god, with a *volumen* (or roll of paper or parchment on a stick) in the left hand, leaning on his staff, round which is coiled the serpent, the symbol of prudence and renovation. Close to the staff is a child, supposed to be Camillus or Telesphorus, the genius of recovery, in the act of bringing the offering of a cock in his left hand and holding in his right hand a small knife with a pointed blade. The well enjoyed a reputation for the salubrity of its water, and this fact explains, no doubt, the presence in its precincts of the statue of the god of medicine, under whose special protection such wells were placed. The worship of Æsculapius is said to have been introduced into Rome from Epidaurus about 293 B.C., but this statue, which is of indifferent workmanship, belongs to a much later period, probably the first or second century of the Christian Era.

Antirabic Institute in Florence.

In this institution, founded through the initiative of Professor Grocci and inaugurated in January, 1899, the medical staff had subjected to the Pasteur treatment up to Nov. 15th, 1900, 591 persons who had been bitten by animals suffering, or suspected to be suffering, from hydrophobia. Advice was given in 957 cases at the request of private individuals or of communal authorities, and diagnostic experiments were carried out on 235 animals sent to the institute with the object of ascertaining whether or not they were hydrophobic. The institute forms a section of the General Medical Clinic of Florence and is under the care of Dr. Daddi and two assistants. The charge for a course of treatment is 50 lire.

(not quite £2), but the poor, wherever they may come from, are treated gratuitously.

Dec. 1st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Housing of the Poor in New York City.

ONE of the most important commissions ever appointed in this city is now sitting. The problem of housing the poor in a sanitary and decent manner has for long been a stumbling-block to municipalities and philanthropists in all the large towns of the world. In New York, owing to the lack of space available, it presents itself in an aggravated form. In truth, too, it must be said that public and private enterprise has lagged strangely in trying to improve existing conditions. However, it seems now that the State authorities of New York have resolved to grapple with the difficulty in a serious manner, and as an earnest of this Governor Roosevelt some little time ago appointed a representative commission to inquire closely into the whole matter. The first of the hearings dealt with the question as to the bearings of the question on tuberculosis, and, as may well be imagined, came to the conclusion that the construction of airy, properly ventilated, hygienic tenements would go far towards checking the development and spread of that scourge. No more effective preventive measures than providing the poor with the means of living in a fairly healthy manner could be undertaken. The second hearing considered the construction of the tenements as regards size, dark hall-ways, badly built air-shafts, and the like. The commission for some months past has been collecting evidence from builders, sanitary experts, and others who possess views on the subject. As may be believed, the advice tendered has had an extremely wide range, the opinions of the various witnesses being in some instances as diverse as the poles. In fact, such a flood of advice has rushed in that it probably has been the cause of a certain amount of embarrassment to the commissioners The tenement laws of other countries have been carefully studied for the purpose of comparison. But, after all, the conditions in New York and in any American or European city are so different that while, doubtless, the commission will see fit to advise the adoption of some of the methods used in housing the poor in other large centres of population, in the main it will conclude that New York must strike out a line of her own and in erecting tenements must adapt herself to her environment. These remarks will be better understood when it is stated that Greater New York has more than 86,000 tenements with 2,250,000 tenants inhabiting them. The commission will also have regard to the subject from the moral standpoint. The overcrowding in New York is almost beyond comprehension, and the assertion is made that at the present time in the Italian quarter 40 families are existing in flats built to contain 16. Of course, this is as immoral as it is contrary to the laws of health. The *New York Sun*, in an editorial article treating of the Tenement Commission, says: "New York's housing problem is the problem of its metropolitan growth, not easy to solve, but to be solved at any cost, for at bottom it is the question of the home from which proceeds citizenship, good or bad as the home may be." London has been wrestling with the problem for many years, and although fairly successful has by no means yet reached a final solution. Consequently she will take an intelligent and kindly interest in the struggles of her big sister on this side of the water to improve the conditions of her poor. The prediction may be safely made that the New York Tenement House Commission will effect much towards this desirable end.

Separate Prisons for Consumptive Convicts.

In the United States it has long been recognised that neither the convicts who are suffering from consumption nor those who are compelled to live in close proximity to them are quite fairly treated. The hygiene of a prison is too often neglected. The offender against the law has, of course, no choice as to his accommodation but must live wherever the authorities wish, whatever the conditions may be. Dr. Rohe, a prominent writer on hygiene, says: "The mortality of convicts, even in the best regulated prisons where especial attention is paid to sanitary requirements of such buildings, is three times as great as among workmen in mines, confessedly one of the most dangerous occupations. More convicts die of consumption than of all other diseases combined." Dr. Rohe puts the mortality from this cause at from 40 to 80 per cent of these deaths. Dr. W. H. Blake, physician on the Board of Inspectors of Convicts for Alabama, has protested many times against this heartless treatment of prisoners, and recently he read before the Medical Association of the State of Alabama a paper treating of the matter. He states that in Alabama the record of deaths for State convicts covers a period of 18 years. For the first half of this period consumption caused 20 3 per cent. of the total mortality; for the last half it caused 42 per cent. In the penitentiaries of different States, of the total deaths the percentage caused by consumption is as follows: Mississippi, 20 per cent.; Arkansas, 20 per cent; Florida, 30 per cent.; Ohio, 31 per cent.; Michigan 33 per cent.; Alleghany County Workhouse, Pennsylvania, 33½ per cent.; Virginia, 41 per cent.; Kentucky, 42 per cent.; Joliet, Illinois, 70 per cent.; Huntsville Penitentiary, Texas, 66 per cent.; Rusk Penitentiary, Texas, 33 per cent.; Washington, 16 per cent.; Connecticut—1898, 60 per cent., and in 1897 every death that occurred in the penitentiary of Connecticut was caused by consumption." It is now an established fact that under favourable conditions tuberculosis can be transmitted from person to person, and, as Dr. Blake points out, prisons afford these conditions in a strikingly favourable manner. For example, in the prisons of Alabama convicts are not kept in separate cells, but from 50 to 100 are confined together in a single large 'cell.' Consumptive convicts, unless acutely ill, are confined in the same cells as the healthy convicts. Dr. Blake suggests as the only remedy for this condition the separation of the consumptive from the non-consumptive convicts. Something more is needed than separate wards in the same building or separate buildings on the same grounds. A separate camp should be provided for consumptive convicts, the farther from the other prisons the better, in order to give the non-tuberculous prisoners the greatest possible immunity from the disease. It is argued, and rightly too, that the State has a right to deprive the offender of his liberty but that it has not the right to deprive him of his health.

Mosquitoes and Yellow Fever.

It will probably be remembered by many readers of THE LANCET that several years ago—in 1882—a physician practising in Havana advanced the theory that a species of mosquito was the agent of transmission of yellow fever. Dr. Finlay, the medical man in question, who still strongly adheres to his belief, does not look upon the mosquito as the intermediate host of yellow fever, but he holds that the mosquito is capable of transmitting the disease directly to man. Other investigators since the time that Dr. Finlay broached his daring opinions have declared views more or less to the same effect. However, but little notice has been taken of these statements, and probably had it not been for the success attending the researches of Manson, Ross, and others in demonstrating to the satisfaction of the majority of scientific men that mosquitoes were chiefly responsible for the dissemination of malaria the matter would not have come to the front now. Encouraged by the favourable results attending the investigations of the malaria problem and anxious to drive out yellow fever from this part of the world a commission of United States army surgeons have for some time been working in Havana. The surgeons comprising the commission were Dr. Reed (surgeon, U S.A.) and Dr. James Carrol, Dr. A. Agramonte, and Dr. Jesse W. Lazear (acting assistant surgeons, U.S A.) Dr. Reed read a paper before the Public Health Association at its last meeting in Indianapolis, Ind., in which the conclusions reached by the commission were stated. These conclusions were as follows. Treating of the bacteriology of the disease: (1) The blood taken during life from the general venous circulation on various days of the disease in 18 cases of yellow fever successfully studied has given negative results as regards the presence of bacillus icteroides (Sanarelli); (2) cultures taken from the blood and organs of 11 yellow fever cadavers have also proved negative as regards the presence of the bacillus; and (3) bacillus icteroides (Sanarelli) stands in no causative relation to yellow fever, but when present should be considered as a secondary invader in this disease. As regards the part played by mosquitoes in the propagation of yellow fever the commission state their conclusions thus: "The mosquito serves as the intermediate host for the parasite of yellow fever and it is highly probable that the disease is only propagated through the bite of this insect." It should also be said that the singing mosquito, culex fasciatus (Fabr.), was identified. The space at my disposal is too limited to describe the experiments which led to the foregoing deductions, and it would be premature to express a definite opinion on the matter. This much, however, may be remarked without prejudice, that experiments will have to be conducted on a larger scale, and the whole question must be more closely investigated ere the assertion that "it is highly probable that the disease is only propagated through the bite of the mosquito" will be generally accepted. The commission have done excellent work and deserve well of their country. I regret to say that two of the members of the commission—Dr. Lazear and Dr. Carrol—fell victims to their unselfish devotion. Both contracted yellow fever while pursuing their experiments and Dr. Lazear succumbed to the disease.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Sanitary State of Sydney.

IF Sydney is not made a sanitary city it will not be for want of reports as to its condition. Quite recently reports were published from the medical officer of the Sewerage Board and from the city health officer, and now another has been presented by Dr. W. G. Armstrong, the Government officer of health of the metropolitan combined sanitary districts, and dealing with a much larger area, including not only the city of Sydney but 40 suburban boroughs and seven adjacent municipalities in the neighbourhood of Parramatta with a population of 456,320. The report deals with the year 1899, its publication having been delayed by the outbreak of bubonic plague, which engaged all the energies of the medical officer for the time being. The report states that all the local authorities are hampered in their administration of the Health Act by want of funds, as the Act does not give powers to raise the necessary means by a special sanitary rate and the ordinary incomes of municipalities are already ear-marked for other purposes. Sydney is one of the most lightly taxed of all large cities and could well support a tax for sanitary purposes. Dr. Armstrong has corrected the returns of the Registrar-General as to vital statistics by obtaining the domicile of all persons dying in the metropolis, and properly distributing them, and he finds that the proper death-rate of the metropolis is 12·39 per 1000. The deaths from typhoid fever were more numerous in 1899 than in the previous year, as were those from phthisis. There was a remarkable decline in the incidence of diphtheria, of diarrhœal diseases, and of scarlet fever. Nearly twice as many cases of typhoid fever occurred in the unsewered districts as in the sewered—viz., one case of typhoid fever to 160 sewered dwellings and one case to 84 unsewered dwellings, notwithstanding that poverty and overcrowding were greatest in the sewered districts, and that in the city of Sydney itself the connexions with the sewers were very faulty. Some improvement was noted in the condition of dairies and the number classed as "bad" had been reduced from 57 to 34, but the existence of 34 badly kept dairies out of a total of 503 is a serious reflection upon the manner in which the Dairies Supervision Act is administered by the local authorities. Concerning common lodging-houses, Dr. Armstrong reports that some were unfit for habitation altogether and others were unfit for use as lodging-houses. The chief faults found were insufficiency of ventilation, paucity of sanitary accommodation, and overcrowding The need of securing more efficient sanitary inspectors is strongly insisted upon. The first step is to give these men security of tenure and to pay them a fair salary, and for the Government to assume control over their appointment and dismissal. During the year Dr. Armstrong gave a series of 15 lectures on sanitation and sanitary law to sanitary inspectors, and at the end of the course an examination was held. On the whole the report is satisfactory.

The Australian Natives Association and the Profession in New South Wales.

The board of directors of the Australian Natives Association have had a conference with the council of the New South Wales Branch of the British Medical Association with reference to the recent resolution passed by the branch practically prohibiting its members from acting as medical officers to the Australian Natives Association. Four delegates were appointed by each side, and Dr. W. H. Coutie, President of the Branch, was voted to the chair. The delegates of the Australian Natives Association presented their views, claiming that the association should be placed on exactly the same footing as the other friendly societies with regard to medical services. The medical delegates agreed to consult with the council of the New South Wales Branch of the British Medical Association and to report the result.

Farewell to Dr. Laure.

Dr. Laure, after practising for 32 years in Sydney, is leaving for France, his native country. Before his departure he was entertained at a banquet by a company of representative citizens, including members of the medical profession, well-known musicians, and a large proportion of the "Colonie Française" in Sydney. The chair was occupied by the Acting Consul-General for France who, in proposing Dr. Laure's health, referred to his good work as a principal medical officer of the marine and his ability and self-sacrifice in the practice of his profession, especially during a time of epidemic, for which he was decorated. During 14 years at St. Vincent's Hospital in Sydney he had done splendid work, and as President of the French Benevolent Society since its foundation he had won the gratitude of all who had come under his care. He had a sincere love of the fine arts and had won the warm friendship of a wide circle. Dr. C. MacLaurin spoke on behalf of the medical profession, the members of which had nothing but the highest esteem for Dr. Laure, who was honourable, upright, and straightforward and a most desirable colleague. Dr. Laure was presented with an illuminated address from the French community expressive of their regard and good wishes.

Death of Dr. J. W. Hester.

Great regret has been felt in Sydney and Newcastle at the untimely death of Dr. J. W. Hester. Dr. Hester was born in 1865 and was educated at the Sydney University, where he graduated as M.B. and Ch.M., obtaining honours in every subject every year and winning the Renwick Scholarship and gold medal. He settled in practice at Stockton, where he remained for 10 years, during the greater part of which he was surgeon to the Newcastle Hospital. Upon the departure of his brother-in-law, Dr. R. Scot Skirving, for South Africa, Dr. Hester came to Sydney to carry on Dr. Skirving's practice and was appointed assistant surgeon to the Prince Alfred Hospital. He had hardly been established in Sydney before he was attacked with a serious affection of the heart which proved fatal. Dr. Hester was held in high esteem in Stockton and he took an active part in many public movements. He was especially a prominent figure in all kinds of athletics and was an officer of almost every amateur sporting and athletic club in the district.

A Case of Hernia into the Foramen of Winslow.

In the *Australasian Medical Gazette* for October is recorded a very interesting and rare case of intestinal obstruction due to hernia of the transverse colon into the foramen of Winslow. The patient, a woman, 47 years of age, was seen by Mr. H. J. F. Groves of Broken Hill, with symptoms of intestinal obstruction, and then by Dr. R. Humphrey Marten of Adelaide, in consultation. The symptoms began on May 10th, and on May 17th, as they had not improved, operation was decided on. The symptoms were: no action of the bowels since May 10th, vomiting, constant regurgitation of sour, frothy liquid, and slight but increasing distension, with borborygmi, stopping short on the right of the middle line below the liver, where there was tenderness. When the abdomen was opened dark red-coloured serous fluid escaped. The sigmoid and descending colon were empty, the cæcum and ascending colon were greatly distended, and on being followed up the distended transverse colon passed under the liver and under a band which was found to be the front wall of the foramen of Winslow, with the hepatic artery pulsating in it. The gut was easily withdrawn. The intestines were so distended and paralysed that a double enterotomy was performed. The small intestine was opened, emptied, closed with sutures, and returned; the cæcum was stitched to the wound and opened; and an artificial anus was formed which has remained permanent and at the request of the patient has not been closed, as it acts as a safety-valve in case of recurrence of obstruction, as has happened.

Nov. 4th.

Obituary.

GEORGE HUTCHINSON MILNES, M.D. CANTAB., L.R.C.P. Edin., M.R.C.S. ENG., LATE R.N.

DR. MILNES, who died on Dec. 3rd from the effects of an overdose of morphia administered by himself for the relief of toothache, was a well-known and respected practitioner in Derby. He received his early education at Repton School and afterwards studied at Cambridge and at St. George's Hospital. In 1880 he become a Member of the Royal College of Surgeons of England, and in June of the following year was appointed house physician at St. George's Hospital. In 1882 he obtained the post of house physician at Addenbrooke's Hospital, Cambridge, where he stayed till the end of 1884. A few months later he graduated at the University, first as Bachelor of Arts and subsequently as Bachelor of Medicine. In 1886 he entered the Royal Navy as surgeon. While in medical charge of H.M.S. *Starling* he took part in the defence of Suakim against the Dervishes (from October to December, 1888), and was present in medical charge of the Naval Brigade at the action of Gemaizeh on Dec. 20th, for which he received the Egyptian war medal with the Gemaizeh clasp and the Khedive's bronze star.

On his return to England in 1890 he was appointed surgeon to the Royal Naval Hospital at Haslar and assistant instructor in hygiene. This position he held but a short time, and on resigning his office gave up his commission. He then, in 1891, took the degree of Doctor of Medicine at Cambridge and four years later was appointed physician to the Derbyshire Royal Infirmary, a position which he held at the time of his death. He also hold the post of consulting physician to the Derbyshire Hospital for Women During his four years' service in the Royal Navy he specially interested himself in the study of fevers prevalent on the shores of the Mediterranean and Red Seas and contributed to THE LANCET some notes on this subject.

ALEXANDER DEAS DAVIDSON, M.A., M.D. CANTAB., M.R.C.S. ENG., L.S.A.

DR. ALEXANDER DEAS DAVIDSON died at his residence, Northampton-place, Swansea, on Dec. 7th, after a short illness, from acute phthisis. The deceased, who was educated at Clare College, Cambridge, graduated B A. with honours at Cambridge University in 1872, and three years later he was admitted M A He received his medical education at St Thomas's Hospital and took the M.R C S Eng. and L S.A. qualifications in 1877, and in 1880 graduated M.D. of Cambridge. After holding the appointments of resident clinical assistant at the Bethlem Royal Hospital and ophthalmic assistant at St Thomas's Hospital, Dr. Davidson commenced practice in Swansea in 1882 Shortly afterwards he was appointed medical officer to the out patient department of the Swansea General and Eye Hospital, and later ophthalmic surgeon to that institution. Dr. Davidson, who was only 51 years of age at the time of his death, will be much missed in Swansea, where he had gained a reputation as a skilful ophthalmic surgeon.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Henry D Noyes, Professor of Ophthalmology in the Bellevue Hospital Medical College, New York,—Dr. Podrez, Professor of Clinical Surgery in the University of Kharkoff.—Dr. Gustav Hartlaub, a well known Bremen practitioner, who was an authority on ornithology, has died at the age of 86 years.

MEDICAL ATTENDANCE ON SEAMEN.—At the Cardiff County Court on Dec. 6th, before Judge Owen, the committee of the *Hamadryad* Seamen's Hospital sued the Bristol Steamship Navigation Company for medical attendance upon a seaman in defendant's employ whilst in the hospital for 72 days. Evidence showed that the ship owned by defendants arrived at Cardiff on Feb. 3rd and that the man was injured whilst on board the following day His honour gave judgment for defendants with costs, holding that shipowners are not responsible for injuries received by a seaman whilst in port, but having regard to the importance of the question leave to appeal was granted.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, DEC. 5TH.

THE Council met again to-day, Sir WILLIAM TURNER presiding. For nearly two hours the proceedings were conducted *in camerâ*.

Inspection of the Final Examinations.

The PRESIDENT announced that Sir George Duffey had accepted the appointment of inspector of final examinations for the year 1901

The Examinations of the Apothecaries' Hall of Ireland.

The PRESIDENT also announced that Dr. W. Parker Herringham, M.D Oxon, F.R.C.P. Lond., assistant physician to St. Bartholomew's Hospital, had accepted the appointment of inspector of the examinations of the Apothecaries' Hall of Ireland.

Restoration to the Medical Register.

The PRESIDENT further announced that the Council had instructed the Registrar to restore the name and qualifications of Mr. Robert Ingram Robertson to the Medical Register.

The Examinations of the Apothecaries' Hall of Ireland.

The Council resumed the consideration of the motion that the reports of the Examination Committee on the Inspection of the July and October examinations of the Apothecaries' Hall of Ireland be received and entered on the minutes.

Mr. TICHBORNE took exception to several passages in the report on the inspection of the October examination and moved that they be deleted, and Mr. BROWN seconded the motion

Sir DYCE DUCKWORTH, speaking as Chairman of the Examination Committee, said that he objected to the omission of any part of the report. It was well known that this body had given the Council an immense amount of trouble and anxiety and that for years it was a body under considerable suspicion.

Mr. TICHBORNE objected to these observations because he said this examination body never did receive any condemnation; it was another examination body, conjoint with the Apothecaries' Hall, and he considered it extremely unfair of Sir Dyce Duckworth to make these observations.

Sir DYCE DUCKWORTH said it was this body in conjunction with another body whose examination came under the very severe condemnation of this Council, and as the result this body became subject to the authority of this Council. The examinations were held by order of the Privy Council under the ægis of this Council and therefore they had to watch very closely the work done. In these reports the Examination Committee had to do something more than merely reflect the opinions of their inspector. They had to analyse and to inquire and to put a clear and unvarnished statement before the Council. He was now speaking for the last time as the Chairman of the Examination Committee and he wished to say this most distinctly. The committee did not exist to please any body but to do their duty.

The proposal of Mr. TICHBORNE to delete certain passages was rejected by a large majority. Subsequent proposals to delete upon a smaller scale were also rejected and thereafter the motion to receive the reports and enter them on the minutes was adopted by the Council.

Dr. ATTHILL moved:—

> That the opinion of counsel be taken as to whether any examiner appointed to take part in the examinations held by the Apothecaries' Hall of Dublin for their registrable qualifications, other than the governor, deputy governor, and director of the said Hall, being the examiners authorised by the Act 31 Geo III, should not in accordance with the terms of the Medical Act (1886) be appointed by this Council.

He had no animus against Apothecaries' Hall and he did not wish to put it either to expense or trouble, but he desired the law made clear and the Hall complying with the law.

Dr. BENNETT, in the absence of Dr. LITTLE, seconded the motion.

Mr. TICHBORNE protested against this proposed waste of the Council's money. As for Dr. Atthill's statement about his good wishes to the Hall, he was afraid it would be received with smiles in Dublin. Mr. Tichborne then proceeded to argue that under certain ancient Acts the Hall had practically a free hand in the matter of appointing examiners.

Dr. McVail rising to a point of order asked the President whether this Council had anything whatever to do with any Act antecedent to the Medical Act of 1858. If anybody in Ireland thought that the Apothecaries' Hall was not acting legally and felt aggrieved then that body could take the matter before the Four Courts in Dublin.

The President said it was difficult for him to say whether from the point of view taken by Dr. McVail this matter was or was not in order. It raised a legal question and it was not for him to give an opinion upon a legal question.

Dr. Atthill said that he held that it was this Council who were aggrieved, whose rights were being infringed. So long as the Hall kept to its governors and directors this Council had no *locus standi*, but when the Hall went beyond them he contended it was for this Council to appoint the examiners.

Several members urged that the matter should be postponed until next session.

Mr. Tichborne said that the whole question had been thoroughly discussed and examined before the Privy Council and he assured the General Medical Council that in all they had done his body had acted within their rights.

The President said he would go so far as to say this, that if this motion, or any motion on the same lines, were sent to him by Dr. Atthill with a view to discussion on another occasion he would ask Mr. Muir Mackenzie to advise him as to its competency.

Dr. Atthill said that if it were understood that the President would ask the advice of Mr. Muir Mackenzie before next session in May that would satisfy him.

The President: You must send the motion to me.

On this understanding Dr. Atthill withdrew his motion.

Prevention of Personation.

On the motion of Mr. Horsley the following report of the Committee upon the prevention of personation was received and entered on the minutes:—

> In the opinion of the Solicitor the Council is fully empowered, under Section XIV, Medical Act, 1858, to frame and enforce the proposed regulation that applications for registration must be made in the handwriting of the applicant on an official form.

In making his motion Mr. Horsley regretted that he had to drop discussion of the personation question for this session because the business hours of the session had been squandered on what he should call squalid business. He promised, in answer to Dr. MacAlister, that he would see that the Council were supplied with the text of the case submitted to the solicitor and copy of the reply thereto.

Regulations for Diplomas in Public Health.

A report of the proceedings of the whole Council in committee on the regulations for diplomas in public health was brought up by Dr. MacAlister, as chairman, and was agreed to.

Mr. Teale then moved that the following be the General Medical Council's

RESOLUTIONS AND RULES FOR DIPLOMAS IN PUBLIC HEALTH FROM THE 1ST OF JANUARY, 1902.
